## ACKNOWLEDGEMENT

I would like to present my sincere gratitude to Assoc. Prof. Dr. Özge KERKEZ KUYUMCU, who supported me throughout my master's degree process for writing and managing projects and was the main person in the development of my thesis.

I would like to express my gratitude to my co-advisor Prof. Dr. Atif KOCA for his laboratory support and guidance.

I would like to thank Res. Asst. Rabia Nur BOZKURT not only for her support but also for her friendship.

I would also like to thank my friends Sumru KALAÇ, İlayda İŞLEK, Sergen BAHMAL, Nida ELMALI, Elif Tuğba YILMAZ, Elif ÇUBUĞUUZUN, who always gave me positive support throughout my master's degree process.

I would like to thank The Scientific Research Commissions (BAPKO) of Marmara University for the project titled "Modifiye Kalkojenitlerin Sentezi, Tanımlanması ve Fotokatalitik Aktiviteleri" (Project Number: FYL-2024-11093).

I would like to thank Scientific and Technological Research Council of Turkey (TUBITAK) for supporting my thesis and serving as a scholar in the project titled "Cd<sub>x</sub>Zn<sub>1-x</sub>S/Farklı İkili Yardımcı Katalizörlerin Sentezi ve Fotokatalitik H<sub>2</sub> Üretiminde Aktivitelerinin İncelenmesi" (Project Number: 123M629), which is a 1002 - A Rapid Support Module.

I would also like to thank TUBITAK again for being supported by the 2210-A Domestic General Master's Scholarship Program during my master's degree.

Finally, I would like to thank my dear mother Emine KABA, my dear father Zeki KABA, my brothers Havvanur and İlkey KABA, My uncle Bayram ÜRESİN, his wife Nurhayat ÜRESİN and my cousin Gamzenur ÜRESİN for their endless love and support.

July, 2024

İbrahim KABA

## ABSTRACT

### SYNTHESIS, CHARACTERIZATION AND PHOTOCATALYTIC ACTIVITIES OF MODIFIED CHALCOGENIDES

Hydrogen is a promising energy source for addressing environmental issues and photocatalytic hydrogen production from water is a promising renewable energy process. Cadmium sulfide (CdS) is a widely used photocatalyst; however, the photocorrosion problem causing the low stability and fast charge recombination problem causing the low photocatalytic activity are also well-known. To prevent the stability problem,  $Cd_xZn_{1-x}S$  which has tunable optical properties has become forward.  $MoS_2$  is used as an additive to semiconductor photocatalysts due to its wide contact interface, inhibition of charge recombination, low cost, high reactivity for  $H_2$  evolution reaction, and enhancement of visible light response. Transition metal carbides such as  $Mo_2C$  are excellent electrocatalysts for the production of  $H_2$ ; additionally, they serve as good co-catalysts for most photocatalysts.

Modified  $Cd_xZn_{1-x}S$  photocatalysts were examined in hydrogen production under solar illumination. In the first part of the study,  $Cd_xZn_{1-x}S$  was prepared using 1,3-diaminopropane (DAP) and then  $MoS_2$  added; in the second part of the study  $Cd_{0.7}Zn_{0.3}S$  nanorod was prepared using ethylenediamine (EDA)/water and then  $MoS_2$  and  $MoC-Mo_2C$  were added. Catalysts were characterized by XRD, TEM, SEM, UV-Vis DRS, and electrochemical applications. For the first part, a full factor design was carried out via Minitab 19 to investigate the factors affecting the produced hydrogen amount. Cd/Zn ratio,  $MoS_2$  content, and photocatalyst loading were studied. Photocatalytic hydrogen production results were analyzed by ANOVA (Analysis of Variance) and it was concluded that for maximum hydrogen production, Cd/Zn ratio should be in the range of 0.5/0.5 and 0.7/0.3;  $MoS_2$  content should be in the range of 2-4% and photocatalyst loading should be 10 mg. For the second part,  $Cd_{0.7}Zn_{0.3}S$  nanorods were modified with various amounts of  $MoS_2$  and  $MoC-Mo_2C$ . N- $Cd_{0.7}Zn_{0.3}S/1\% MoS_2/1.0\% MoC-Mo_2C$  catalyst showed the best result with  $133.5 \text{ mmol } H_2 \text{ g}^{-1} \text{ h}^{-1}$ , while the hydrogen production rate of N- $Cd_{0.7}Zn_{0.3}S$  was  $37.2 \text{ mmol } g^{-1} \text{ h}^{-1}$ .

## ÖZET

### MODİFİYE KALKOJENİTLERİN SENTEZİ, KARAKTERİZASYONU VE FOTOKALİTİK AKTİVİTELERİ

Hidrojen, çevresel sorunları çözecek, umut vadeden bir enerji kaynağıdır ve sudan fotokatalitik hidrojen üretimi umut vadeden bir yenilenebilir enerji sürecidir. Kadmiyum sülfür (CdS) yaygın olarak kullanılan bir fotokatalizördür; ancak, düşük kararlılığa neden olan fotokorozyon sorunu ve düşük fotokatalitik aktiviteye neden olan hızlı yük rekombinasyonu sorunu da iyi bilinmektedir. Kararlılık sorununu önlemek için, ayarlanabilir optik özelliklere sahip  $Cd_xZn_{1-x}S$  öne çıkmıştır.  $MoS_2$ , geniş temas yüzeyi, yük rekombinasyonunu engellemesi, düşük maliyeti,  $H_2$  oluşumu reaksiyonu için yüksek reaktivitesi ve görünür ışık tepkisinin iyileştirilmesi nedeniyle yarı iletken fotokatalizörlere katkı maddesi olarak kullanılır.  $Mo_2C$  gibi geçiş metali karbürleri,  $H_2$  üretimi için mükemmel elektrokatalizörlerdir; ayrıca, çoğu fotokatalizör için iyi yardımcı katalizörler olarak hizmet ederler.

Modifiye edilmiş  $Cd_xZn_{1-x}S$  fotokatalizörleri solar ışık altında hidrojen üretiminde incelenmiştir. Çalışmanın ilk bölümünde,  $Cd_xZn_{1-x}S$ , 1,3-diaminopropan (DAP) kullanılarak hazırlanmış ve ardından  $MoS_2$  eklenmiştir; çalışmanın ikinci bölümünde,  $Cd_{0.7}Zn_{0.3}S$  nanoçubuklar, etilendiamin (EDA)/su kullanılarak hazırlanmış ve ardından  $MoS_2$  ve  $MoC-Mo_2C$  eklenmiştir. Katalizörler XRD, TEM, SEM, UV-Vis DRS ve elektrokimyasal uygulamalarla karakterize edilmiştir. İlk bölümde, üretilen hidrojen miktarını etkileyen faktörleri araştırmak için Minitab 19 aracılığıyla tam faktör tasarımı gerçekleştirilmiştir. Cd/Zn oranı,  $MoS_2$  içeriği ve fotokatalizör yüklemesi incelenmiştir. Fotokatalitik hidrojen üretim sonuçları ANOVA (Varyans Analizi) ile analiz edilmiştir ve maksimum hidrojen üretimi için Cd/Zn oranının 0.5/0.5 ile 0.7/0.3 aralığında;  $MoS_2$  içeriğinin %2-4 aralığında ve fotokatalizör miktarının 10 mg olması sonucuna varılmıştır. İkinci kısım için,  $Cd_{0.7}Zn_{0.3}S$  nanoçubuklar çeşitli miktarlarda  $MoS_2$  ve  $MoC-Mo_2C$  ile modifiye edilmiştir. N- $Cd_{0.7}Zn_{0.3}S/1\%$   $MoS_2/1.0\%$   $MoC-Mo_2C$  katalizörü  $133.5 \text{ mmol } H_2 \text{ g}^{-1} \text{ h}^{-1}$  ile en iyi sonucu gösterirken, N- $Cd_{0.7}Zn_{0.3}S$ 'nin hidrojen üretim hızı  $37.2 \text{ mmol } g^{-1} \text{ h}^{-1}$ 'dir.

## **1. INTRODUCTION**

Hydrogen is a viable energy source that can help solve environmental and energy issues [1]. Hydrogen has the highest specific energy among fuels. It is regarded as a worldwide energy solutions leader since the combustion process of hydrogen produces only water [2]. It has been extensively researched as an energy source due to its high energy density and minimal environmental effect [3]. It is accepted as a potential fuel due to the advantages of its use as a carbon-free solution, it can be used in transportation infrastructures and existing fuel storage, and its advantages can be mentioned as being suitable for long-term storage [4].

Green hydrogen, which is not dependent on fossil fuels, emits little or no carbon dioxide during manufacturing, making it renewable and clean. Today, renewable energy sources like solar and energy are employed in a variety of ways, as are ethanol, biogas, and wood. Green hydrogen generation is being investigated utilizing biomass-derived raw materials [5]. Hydrogen, whose only result when burnt is  $H_2O$ , has gained popularity as a clean energy carrier [6]. In terms of both challenges (fossil fuel depletion and toxic gaseous byproducts of fossil fuels), hydrogen generation using solar energy is seen as a very promising technology, and research is now underway. Among solar hydrogen generation techniques, semiconductor-based photocatalytic hydrogen production is regarded as a successful approach since it allows for the easy use of artificial indoor illumination or solar energy, resulting in widespread availability. As a result, significant efforts are being made to produce efficient, stable, low-cost, and environmentally friendly photocatalysts that use solar energy to provide additional hydrogen sustainably [7].

## **2. LITERATURE REVIEW**

### **2.1. Photocatalytic Hydrogen Production and Mechanism**

Photocatalytic hydrogen generation is one of several renewable hydrogen production processes.

The utilization of sunlight as a light source, as well as semiconductor catalysts that support it, is an important area of research in turning solar energy into chemical energy. Water splitting employing semiconductor photocatalysts is regarded as a promising and

environmentally friendly method for photocatalytic hydrogen generation [8]. In this process, solar energy is used to produce valuable chemical fuels such as hydrogen from the decomposition of water via a photocatalytic reaction involving a semiconductor, and research is being conducted to identify suitable semiconductors for this purpose, including metal oxides, metal hydroxides, oxynitrides, and sulfides [9][10]. High hydrogen production efficiency, accessible cost, optimization of bandgap, stability and other factors are considered the key characteristic parameters for water splitting. Inhibiting electron recombination and increasing photostability through the development of new catalysts and co-catalysts are other important research topics [11]. Generally, the photocatalytic H<sub>2</sub> generation process consists of three main steps: the semiconductor absorbs light to form electron-hole pairs, the photogenerated electron-hole pairs are separated and transferred to the surface of the semiconductor, and H<sub>2</sub> evolution on the semiconductor surface. The efficiency of photocatalytic H<sub>2</sub> production depends on the balance of kinetics and thermodynamics between these three processes. Studies are taking important steps to develop innovative photocatalysts with wide absorption spectrum and effective charge separation and transfer [12]. The Gibbs free energy shift for water splitting is + 237.13 kJ/mol, and two simultaneous redox processes occur, as seen in [Equations \(1.1\)](#) and [Equation \(1.2\)](#) below. [Equation \(1.3\)](#) represents the complete reaction [13].

The water decomposition process is a thermodynamically involuntary event, which requires energy input to overcome the 1.23 eV energy barrier. To carry out the photocatalytic breakdown process of water, a semiconductor in the reaction medium must be activated by a photon with energy equal to or higher than its band gap energy. In this situation, electrons transfer from the valence band to the conduction band, leaving holes in the valence band. Photons create electrons (e<sup>-</sup>) and holes (h<sup>+</sup>). If the conduction band

(CB) of the photocatalyst is more negative than the  $H^+/H_2$  reduction potential and the valence band (VB) is more positive than the  $O_2/H_2O$  oxidation potential, the electrons and holes produced by this photon have the capacity to reduce the  $H^+$  cation and oxidize  $H_2O$ , respectively happens [13]. The semiconductor with a shorter band gap absorbs and utilizes sunlight more quickly, whereas the semiconductor with a wider band gap has a greater capacity for oxidation or reduction. Furthermore, the violent recombination of photogenerated carriers within a discrete semiconductor poses a significant hurdle for photocatalyst applications due to the existence of Coulomb forces [14]. Figure 2.1 illustrates the mechanism. The image depicts four steps: 1) light harvesting, 2) charge separation, 3) electron and hole transport to the photocatalyst's surface, and 4) redox reaction [15]. In other words, the conduction band (CB) of an ideal photocatalyst must be more negative than the  $H^+/H_2$  reduction potential, and the valence band (VB) [16].

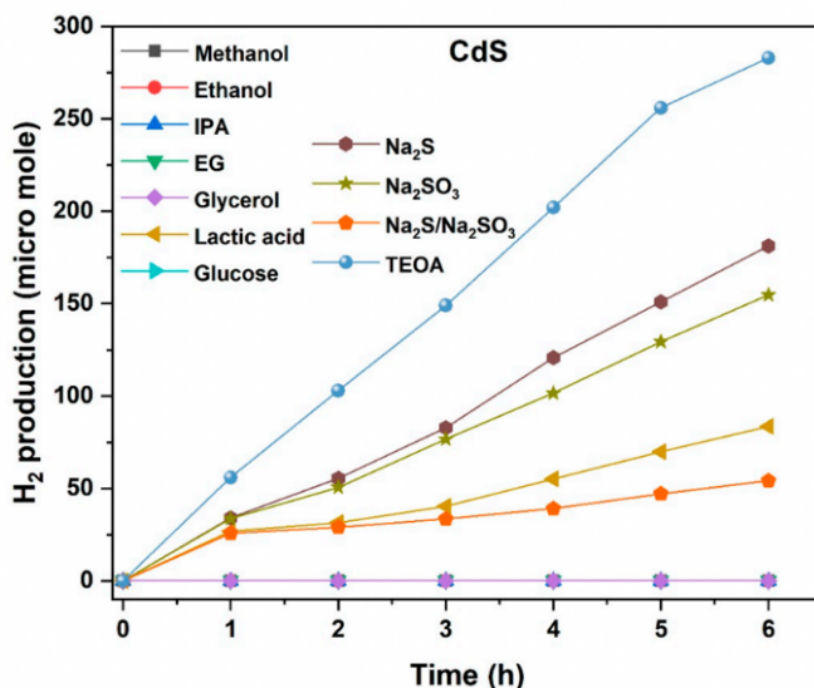

**Figure 2.1** A schematic representation of the photocatalysis process and charge recombination [15].

## 2.2.Sacrificial Agents

Water splitting is an energetically rising process ( $\Delta H = 286 \text{ kJ mol}^{-1}$ ), hence electron or sacrificial agents donor/hole scavengers play an essential role for photocatalytic hydrogen synthesis. The most often used sacrificial reagents for catalysis are methanol, ethylenediaminetetraacetic acid (EDTA), lactic acid (LA), triethanolamine (TEOA), and sodium sulfur/sodium sulfite ( $Na_2S/Na_2SO_3$ ). Among these sacrificial components,  $S^{2-}$

$/\text{SO}_3^{2-}$ , or sulfur ion, has a comparatively strong reducing capacity and is the most utilized [17]. The sacrificial agent is irreversibly oxidized by the photon-generated vacancies instead of the water molecule. It becomes easier for electrons in the conduction band to reduce water and the oxygen ( $\text{O}_2$ ) formation reaction becomes easier. At the same time, thanks to these agents, the back reaction of  $\text{H}_2$  and  $\text{O}_2$  is prevented. The sacrificial reagent helps control the hole recombination and the rate of electron, and the photocatalytic efficiency can be increased by the addition of the sacrificial agent [18]. For example, when examining the CdS photocatalyst, the pH becomes alkaline and produces hydrogen sulfide ( $\text{HS}^-$ ) and sulfide ( $\text{S}_2^{2-}$ ) when dissolved in water. During the process,  $\text{HS}^-$  and  $\text{S}_2^{2-}$  are rapidly oxidized into polysulfide ( $\text{S}_4^{2-}$ ,  $\text{S}_5^{2-}$ ) ions and sulfate ( $\text{SO}_4^{2-}$ ).  $\text{Na}_2\text{SO}_3$  is used to improve efficiency and activity. When the  $\text{H}_2$  generation efficiency of the CdS photocatalyst was investigated using different sacrificial agents (Figure 2.2.), it was discovered that  $\text{Na}_2\text{S}/\text{CdS}$  or  $\text{CdS}/\text{Na}_2\text{SO}_3$  was greater than that of  $\text{CdS}/\text{Na}_2\text{S}/\text{Na}_2\text{SO}_3$ . It has been demonstrated that TEOA produces the most  $\text{H}_2$ , which can be attributed to strong interface connectivity and photo-generated holes on the CdS surface, which improves efficiency [17].

**Figure 2.2** Photocatalytic  $\text{H}_2$  generation efficiency of CdS with varied sacrificial agents [17].

### 2.3. Metal sulfides (MSs)

Among the numerous semiconductor materials studied, metal sulfides (MSs) are promising for H<sub>2</sub> production under obvious light [19].

#### 2.3.1. Cadmium Sulfide (CdS)

CdS photocatalysts come in two crystal structures: cubic and hexagonal. Cubic crystals, also known as zinc blende phases, have a tetrahedral structure in terms of crystal morphology and are classified as equiaxed systems with faces [20]. Having a moderately shrinking band gap (2.4 eV), CdS seems warranted as a perfect photo driven catalyst. Generally, co-catalysts are used to prevent the recombination of photon-induced charges with CdS and improve H<sub>2</sub> production efficiency [21]. It exhibits great mobility, a low band gap, and a good energy band location, making it a prospective high-performance photocatalyst [22]. However, the photocatalytic H<sub>2</sub> production action on an uncovered CdS is extremely low, primarily due to the rapid recombination of photogenerated electrons and holes, the rapid reverse reaction between hydrogen and oxygen, and the large H<sub>2</sub> production overpotential [23]. It is susceptible to photo corrosion, and CdS nanoparticles easily agglomerate, resulting in inactivation. These issues lead CdS to have a poor photocatalytic hydrogen generation rate [24]. As a result, CdS can be paired with a cocatalyst to address some of its issues. Noble metals have a high electron density and strong electrical conductivity, making them useful cocatalysts for photocatalysts. However, its high cost and rarity limit its widespread utilization, hence non-noble metal cocatalysts are being developed [25]. Ma et al. used an atomic layer deposition (ALD) approach to develop a new type of CdS@ZnO core-shell the heterostructure. The rationally built thin ZnO shell not only permits light to be received through the CdS core, but it also forms an intimate heterojunction between the two. The number of deposition cycles controls the amount of ZnO shell coated on the CdS core, and the resultant CdS@ZnO with (100) ALD deposition cycles have a greatest photocatalytic evolution of H<sub>2</sub> rate of 11.36 mmol/g/hour. When Pt and PdS are used as co-catalysts, the H<sub>2</sub> evolution rates are further increased to 71.39 and 98.82 mmol g<sup>-1</sup> h<sup>-1</sup>, accordingly, which are 4.1 and 5.7 times greater than the maximum reported value (17.40 mmol g<sup>-1</sup> h<sup>-1</sup>). The H<sub>2</sub> production and % quantum efficiency of some co-catalysts added to the CdS photocatalyst are given in [Table 2.1](#).

**Table 2.1** Effect of different co-catalysts added on CdS.

Catalyst Type	Catalyst Amount (mg)	Light Intensity (W/m <sup>2</sup> )	Hydrogen		References
			Production Amount (mmol g <sup>-1</sup> h <sup>-1</sup> )	% Quantum Efficiencies	
CdS/MoS <sub>2</sub>	10	300 W xenon lamp	63.7	33.62	26
CdS/ZnS/ZnO	10	225 W Xenon arc lamp	51.4	26.88	27

ZnO/CdS/MoS <sub>2</sub>	15	500 W Xenon lamp	10.3	-	30

### 2.3.2. Zinc Oxide (ZnO) and Zinc Sulfide (ZnS)

Many semiconductors, including zinc oxide (ZnO), zinc sulfide (ZnS), molybdenum disulfide (MoS<sub>2</sub>), and bismuth vanadate (BiVO<sub>4</sub>), have been shown to improve CdS's capacity to evolve H<sub>2</sub> via heterostructures [31]. Wide band gap ZnO, an inorganic semiconductor photocatalytic material, is widely used in different fields, such as biomedicine, sensors, solar cells and photocatalysis, especially in the photocatalytic degradation of organic pollutants; It has features such as being non-toxic, having stable chemical and physical properties, and high catalytic activity. In addition, this material is environmentally friendly and low-cost. They are synthesized in different morphologies (nanorods, nanospheres, nanotubes, nanowires, nanocrystals, etc.). In the studies, zinc

oxide nanoparticles (ZnO-NPs) are used as another important semiconductor photocatalytic material after TiO<sub>2</sub> [32]. ZnS has a greater band gap energy than CdS. ZnS's large band gap energy makes it an ideal surface passivating shell material for CdS [33]. ZnS is a semiconductor of the n-type photocatalyst with a broad bandgap of 3.68 eV. It has a negative redox potential in the conduction band (-1.36 eV) and valence band (+2.35 eV) and is chemically stable against oxidation and hydrolysis [34]. Although it has lower photocatalytic activity than TiO<sub>2</sub>, for example, ZnS is still considered an outstanding semiconductor due to its stability, non-toxicity, fast electron mobility, and rapid formation of photogenerated electron-hole pairs. ZnS's wide band gap of 3.68 eV limits its applicability to UV light ( $\lambda < 400$  nm), like TiO<sub>2</sub> [35]. Lin et al. developed an incompletely coated CdS/ZnS core/shell photocatalyst using a simple hydrothermal technique. Because of the defect energy levels created by zinc vacancies, the normal type-I heterojunction of CdS/ZnS develops to a type-II heterojunction and Z-scheme hybrid structure, allowing the ZnS shell to promptly transfer and collect photogenerated holes from the CdS core. Under optimum conditions, CdS/ZnS produced the most hydrogen (24.1 mmol g<sup>-1</sup> h<sup>-1</sup>) when exposed to visible light. After 9 hours of illumination at  $\lambda = 420 \pm 5$  nm, the average apparent quantum yield is 9.3%. It shows excellent photocatalytic H<sub>2</sub> evolution while being stable [36]. H<sub>2</sub> production and % quantum efficiency of some ZnS photocatalyst samples are given in [Table 2.2](#).

**Table 2.2** Hydrogen production and efficiency values of different ZnS samples.

Catalyst Type	Catalyst Amount (mg)	Light Intensity (W/m <sup>2</sup> )	Hydrogen Production Amount (mmol g <sup>-1</sup> h <sup>-1</sup> )	% Quantum Efficiencies	References
CdS/ZnS	10	300 W xenon lamp	24.1	9.3	36
CdS/ZnS	10	300-W Xe lamp	14.0	2.76	37
ZnO/ZnS/MoS <sub>2</sub>	-	100 W Xe lamp	10.4	25.4	38

### 2.3.3. Cadmium Zinc Sulfide ( $\text{Cd}_x\text{Zn}_{1-x}\text{S}$ )

Based on the studies conducted on the CdZnS structure, it can be said that it is not a physical mixture like CdS/ZnS, but rather a type of solid solution. Due to this feature, it has better properties than CdS, ZnS and CdS/ZnS structures and shows a better photocatalytic activity due to the adjustable band gap [39]. However, the photocatalytic  $\text{H}_2$  production effect on uncoated CdS is negligible, owing to the rapid recombination of photogenerated electrons and holes, the rapid reverse reaction between hydrogen and oxygen, and the significant  $\text{H}_2$  production overpotential. It may be argued that ternary metal sulfides produce substantially superior outcomes in terms of band gap suited for hydrogen production. In comparison to  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  photocatalysts, ternary metal sulfide catalysts produce more hydrogen from water, are more stable, efficient, and have a better form structure. Its characteristics have made it famous in studies nowadays. Changing the  $x$  value can improve photocatalytic activity and yield the best band structure for photocatalytic  $\text{H}_2$  generation [40][41].  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  has a favorable band gap that varies with composition, allowing to produce  $\text{H}_2$  when exposed to visible light.  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  are promising materials for short-wavelength laser diodes and high-density optical recording [42]. Different methods are utilized to synthesize  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  catalysts. The sol-gel procedure is the most extensively utilized method for producing semiconductor photocatalysts. The main advantage of the sol-gel process is the uniform mixing of metal ions at the molecular level, which promotes the production of polycrystalline particles with unique characteristics. The hydrothermal synthesis procedure is often carried out in steel pressure containers (autoclaves) at controlled temperatures and/or pressures using aqueous solutions. Temperatures can climb above the boiling point of water, resulting in vapor saturation pressure. The solvent amount and reaction temperature of solution introduced to the autoclave have a significant impact on the internal pressure generated. The solvothermal method is a variation on the hydrothermal technique in which the solvent is anhydrous. Because of the wide range of organic solvents with high boiling points available, the reaction temperature can be raised far higher than in the hydrothermal approach. In general, the solvothermal technique has been shown to be more effective in controlling semiconductor particle size, shape, distribution, and crystallinity than the hydrothermal method. Compared to the hydrothermal technique, the solvothermal method allows for better control over photocatalyst parameters such as

particle shape and size, crystallization, dispersion, and particle agglomeration behavior. Another crucial consideration in the solvothermal process is the solvent used. The role of the solvent is particularly crucial in this process, as varied physicochemical parameters of the solvent influence [43].

### 2.3.3.1. Parameters Affecting the $Cd_xZn_{1-x}S$ Catalyst

The parameters affecting the synthesized catalyst can generally be listed as follows: Change in cadmium and zinc ratio, autoclave synthesis temperature and parameters, changes in the morphological structure in different sizes and shapes due to the solvent used [44]. These affecting parameters are explained with examples from studies conducted over the years.

The band gap position in the  $Cd_xZn_{1-x}S$  photocatalyst varies as the Cd/Zn ratio changes. The band gap narrows as the cadmium content increases and increases as the cadmium content declines. As the Zn content in the  $Cd_xZn_{1-x}S$  photocatalyst grows, the edge potential of the conduction band decreases, increasing the band gap, which is undesirable for photocatalysis. The efficiency of  $H_2$  generation under visible light can be enhanced by selecting a suitable band gap width and conduction band. Studies conducted with  $Cd_xZn_{1-x}S$  photocatalyst in the literature have revealed that photocatalysts with high Cd content show the highest efficiency because of their low band gap [45][46][47].

Wang et al. (2011) used the solvothermal method to synthesize the  $Cd_xZn_{1-x}S$  photocatalyst with various x ratios as nanorods and investigated its effectiveness in producing hydrogen from water. The study found that as the Cd/Zn ratio changes, the morphological structure changes, which affects the performance of the catalyst. [Figure 2.3.](#) shows the morphological structure change as Cd/Zn levels change. As the amount of  $Zn^{2+}$  increased, the length of the nanorods decreased, and their shape changed from rod-like to plate-like. The  $Zn^{2+}$  content in the precursor solutions was increased to 0.7 and 0.8 (x value) to produce nanoplates and microspheres composed entirely of small particles. As a result, hydrogen production efficiency remained poor even at high cadmium rates. The  $Cd_{0.5}Zn_{0.5}S$  photocatalyst performed the best, with a quantum efficiency of 30.4% and hydrogen production of  $10.97 \text{ mmol g}^{-1} \text{ h}^{-1}$ . The material's exceptional efficiency can be attributed to its fabrication into nanorods. As a result, it has been demonstrated that the morphological structure and nanoforms of the catalyst have a direct impact on its

activity. In this study, the change in the morphological structure of the  $\text{Cd}_{0.5}\text{Zn}_{0.5}\text{S}$  photocatalyst by changing the autoclave solvothermal synthesis temperature is shown. [Figure 2.4](#) shows the change in morphological structure according to the changing solvothermal synthesis temperature. In [Figure 2.4c](#), only all of them were found to be nanorods in the 12 h synthesis. It was shown that 2 or 6 hours was not sufficient, and in the 24 h synthesis period, the nanorod form shifted towards nanoparticles [48].

**Figure 2.3** FESEM images of  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  generated using the solvothermal method at 180 °C for 24 hours [48].

**Figure 2.4** FESEM images of  $\text{Cd}_{0.5}\text{Zn}_{0.5}\text{S}$  sample synthesized with different reaction times, hours increasing in order from a to b (2 hours, 6 hours, 12 hours, and 48 hours) [48].

Li et al. (2013) observed the Cd/Zn ratio of the band gap. Figure 2.5. shows the variation of the band gap according to the Cd/Zn ratio. The causes of visible light absorption and photoactive enhancement for the  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  solid solution were investigated and discussed by observing the changes in the energy distributions, charge distributions, and energies of the band particles. It has been demonstrated that the band gap decreases as the cadmium level increases [49].

**Figure 2.5** Change in conduction and valence band potentials of  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  ( $x = 0, 0.1, 0.3, 0.5, 0.7, \text{ and } 1.0$ ) photocatalyst with Cd/Zn ratio [49].

Wang et al. (2013) investigated the fabrication of  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  complex structures, such as micro flowers and microspheres, utilizing diethylenetriamine (DETA) and water solvents. The morphology of the  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  solid solution changed from micro flowers to microspheres as the Zn concentration increased. The photocatalytic reaction of  $\text{H}_2$  over solid solutions is further studied, with the highest  $\text{H}_2$  evolution rates achieved without co-catalysts at  $1.8 \text{ mmol g}^{-1} \text{ h}^{-1}$ . The morphological shift caused varied BET and surface flaws, which resulted in varying photocatalytic activity. The  $\text{Cd}_{0.2}\text{Zn}_{0.8}\text{S}$  microspheres demonstrated the highest photocatalytic capacity, producing about  $1.8 \text{ mmol g}^{-1} \text{ h}^{-1}$ . After adding 1 wt% Pt to the surface of  $\text{Cd}_{0.2}\text{Zn}_{0.8}\text{S}$ , the speed of  $\text{H}_2$  generation increased to  $5 \text{ mmol g}^{-1} \text{ h}^{-1}$ .

Figure 2.6A displays SEM pictures of produced  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  samples. ZnS nanocrystals in form of pure are composed like microspheres coated with short nanorods. The

photocatalytic activity of  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  solid solution in  $\text{H}_2$  generation was studied in a system containing 0.1 M  $\text{Na}_2\text{S}$  and aqueous  $\text{Na}_2\text{SO}_3$ . All  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  photocatalysts display greater activity than  $\text{ZnS}$  and  $\text{CdS}$ , implying that the formation and structure of the solid solution are important for hydrogen production (Figure 2.6Ba). Noble metals including Pt, Pd, and Rh were investigated as co-catalysts for increasing photocatalytic activity. Pt had the strongest positive effect on  $\text{CdS}$  photocatalytic activity. Adding Pt to  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  photocatalysts increases photocatalytic activity by up to 5  $\text{mmol g}^{-1} \text{h}^{-1}$ , which is nearly 1.8 times greater than the bare  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  solid solution catalyst (Figure 2.6Bb) [50].

**Figure 2.6** (A) SEM images of  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  nanocrystals with changing of x values (x: 0, 0.2, 0.4, 0.6, 0.8, and 1); (B) (a) Hydrogen production of varying solid solution of  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  photocatalysts in using  $\text{Na}_2\text{SO}_3/\text{Na}_2\text{S}$  aqueous solutions. (b)  $\text{H}_2$  evolution of  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  loading with using co-catalyst of Pt adding like 1 wt.% in  $\text{Na}_2\text{SO}_3/\text{Na}_2\text{S}$  aqueous solution [50].

Another parameter that affects photocatalytic activity is the morphological structure of the catalyst. Nanorod structures provide an increase in  $\text{H}_2$  production capacity through water dissociation, where the long axis can offer a unidirectional light-excited electron-hole pair flow and a short transfer distance at the surface. The light absorption and

scattering properties of nanorod structures are generally open to improvement due to their high surface to volume ratios. It increases the activity in the fast and long-term load carrying ability of nanorod structures. With the richness of sulfur vacancies in the CdZnS nanorod photocatalyst, it greatly limits charge recombination thanks to electron capture sites [51]. In their study, Yu et al. (2020) synthesized the  $Cd_xZn_{1-x}S$  catalyst in the form of a nanorod, examined the effectiveness of the catalyst, and found that the catalyst that produced the best hydrogen production was  $Cd_{0.6}Zn_{0.4}S$  and produced  $59.3 \text{ mmol h}^{-1} \text{ g}^{-1} \text{ H}_2$ . The  $Cd_xZn_{1-x}S$  catalyst synthesized in the form of nanorods was compared with CdS and ZnS and it was observed that it produced approximately 30 times more  $\text{H}_2$  than pure CdS. Moreover, in the same study, the  $\text{H}_2$  production results of the CdZnS photocatalyst synthesized as a nanorod could only be achieved by adding 1% Pt co-catalyst onto the CdS photocatalyst. This result shows that the CdZnS photocatalyst synthesized in a nanorod morphological structure provides high activity without using expensive co-catalysts such as Pt. It can be said that nanorod structures increase hydrogen production efficiency.

Wang et al. (2011) described a simple solvothermal approach (Using ethylenediamine (EDA) to CdS and ZnS in the form of a solid solution). The as-prepared affordable photocatalysts exhibit significantly greater hydrogen production activities than previously reported in the absence of additives and cocatalysts.  $Cd_xZn_{1-x}S$  solid solution photocatalysts were successfully synthesized utilizing a simple solvothermal technique with EDA for the solvent and thioacetamide (TAA) for the sulfur source. According to the findings, due to EDA's different coordinating abilities with  $Cd^{2+}$  and  $Zn^{2+}$  ions, as well as its promoting effects on the development of ZnS and CdS, there is an evident morphological progression of the shape of metal complex microplates, leading to nanorods and nanoparticles. The  $Cd_{1-x}Zn_xS$  catalysts were discovered to be homogeneous solid solutions containing  $0.3 \leq x \leq 0.5$  in the precursor solution. Excellent photocatalytic activity was achieved without the use of pricey metal components or co-catalysts. It was discovered to be  $Zn_{0.5}Cd_{0.5}S$ , with a hydrogen generation rate of  $1097 \text{ mmol h}^{-1}$  ( $\lambda \geq 420 \text{ nm}$ ). AQE is almost 30.4% at 420 nm [48]. [Table 2.3](#) shows the results of CDS catalysts used in bare form after research in the literature.

**Table 2.3** Hydrogen production and efficiency values of different bare  $Cd_xZn_{1-x}S$  samples.

Catalyst Type	Catalyst Amount (mg)	Light Intensity (W/m <sup>2</sup> )	Hydrogen Production Amount (mmol g <sup>-1</sup> h <sup>-1</sup> )	% Quantum Efficiencies	References
$Cd_{0.19}Zn_{0.81}S$	5	300 W Xe lamp	7.7	-	52
$Cd_{0.36}Zn_{0.64}S$	50	300 W Xe lamp	0.8	-	53
$Cd_{0.5}Zn_{0.5}S$	100	300 W Xe lamp	11.0	30.4	48
$Cd_{0.6}Zn_{0.4}S$	5	300 W Xe-arc lamp	42.7	17.6	7
$Cd_{0.6}Zn_{0.4}S$	-	300 W Xe lamp	59.3	-	51
$Cd_{0.5}Zn_{0.5}S$	50	1800 W/m <sup>2</sup>	7.4	9.6	54
$Cd_{0.8}Zn_{0.2}S$	200	350 W Xe lamp	0.9	10.3	55

#### 2.4. The Effect of Adding Co-catalysts.

Co-catalysts are added to the catalyst to improve hydrogen production efficiency and productivity. Co-catalysts are frequently used to address these issues, and their functional variety can effectively enhance the improvement of catalytic activity [56]. Metals like Ag, Pt, Ru, Pd, and Au are employed as both photocatalysts and cocatalysts because they have many active sites appropriate for photocatalytic reactions. Pt, as the most widely used co-catalyst, has the highest work function, which means it has the greatest ability to capture electrons from the semiconductor's conduction band and efficiently separate electron-hole pairs, resulting in many active sites for hydrogen evolution [57]. Platinum

is widely used as a photocatalyst for hydrogen evolution reaction (HER) from water, but its rarity and high cost limit its widespread use, necessitating the development of non-noble metal alternatives [58]. Gold, like Pt, is an expensive co-catalyst. Due to the high cost and limited features of these co-catalysts, research is being conducted on co-catalysts capable of replacing precious metals [59]. Studies are exploring the use of noble metal-free materials as co-catalysts for higher hydrogen production at an economic level. Metal chalcogenides are seen as a promising choice due to their unique electrical and optical properties, low cost, and abundant presence in the earth's crust [60]. Molybdenum disulfide ( $\text{MoS}_2$ ), with a layered crystal structure, is considered an alternative for Pt [59].

#### 2.4.1. Molybdenum disulfide ( $\text{MoS}_2$ )

$\text{MoS}_2$ , one of the co-catalysts, is used as an additive to semiconductor photocatalysts due to its wide contact interface, inhibition of charge recombination, low cost, high reactivity for  $\text{H}_2$  evolution reaction, and enhancement of visible light response [47][61][62]. There are few studies in the literature on adding co-catalysts to the  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  catalyst. Zhao et al., (2016) synthesized  $\text{Cd}_{0.5}\text{Zn}_{0.5}\text{S}/\text{MoS}_2$  photocatalyst by hydrothermal coprecipitation method and proposed photocatalyst catalyst showed higher activity and stability with  $12.30 \text{ mmol g}^{-1} \text{ h}^{-1}$  hydrogen under visible light irradiation. Figure 2.7. illustrates the VB and CB edge potentials for  $\text{MoS}_2$  and  $\text{Cd}_{0.5}\text{Zn}_{0.5}\text{S}$  solution. A putative mechanism for increased  $\text{H}_2$  production in  $\text{Cd}_{0.5}\text{Zn}_{0.5}\text{S}/\text{MoS}_2$  photocatalysts is postulated. Once the  $\text{Cd}_{0.5}\text{Zn}_{0.5}\text{S}/\text{MoS}_2$  photocatalyst is exposed to visible light, photogenerated electrons move from the  $\text{Cd}_{0.5}\text{Zn}_{0.5}\text{S}$  solid solution to  $\text{MoS}_2$ , where they are converted into  $\text{H}_2$ , while holes oxidize the sacrificial material. As a result, the co-catalyst  $\text{MoS}_2$  expedited the separation of pairs of electrons and holes, which is crucial for the photocatalytic reaction, while limiting their combination, resulting in considerable  $\text{H}_2$  production for the  $\text{Cd}_{0.5}\text{Zn}_{0.5}\text{S}/\text{MoS}_2$ . However, when excess  $\text{MoS}_2$  is added, the bulk of the  $\text{Cd}_{0.5}\text{Zn}_{0.5}\text{S}$  surface may be coated by  $\text{MoS}_2$  nanosheets, decreasing electron-hole pair formation, or the excess  $\text{MoS}_2$  nanosheets may act as a photogenerated recombination center, leading in low photoactivity. As a result, it has been claimed that adding large amounts of co-catalyst has no positive effect on activity levels [45].

**Figure 2.7** A schematic illustration of the potential and band locations of  $\text{Cd}_{0.5}\text{Zn}_{0.5}\text{S}/\text{MoS}_2$  [45].

Wang et al., (2023) synthesized plate-on-plate structured 0.8%  $\text{MoS}_2\text{-Cd}_{0.6}\text{Zn}_{0.4}\text{S}$  photocatalyst, which showed excellent photocatalytic hydrogen production ( $13.5 \text{ mmol g}^{-1} \text{ h}^{-1}$ ), through an easy electrostatic self-assembly strategy, and the amount of hydrogen production increased by 1.3 times with the addition of  $\text{MoS}_2$  compared to pure  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$ . Thus,  $\text{Cd}_x\text{Zn}_{1-x}\text{S}/\text{MoS}_2$  is a promising noble-metal free binary photocatalyst for hydrogen production and its structural effects on reaction yield is worth investigating [46].  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  decorated with Au nanoparticles made by Chen et al., (2020) was assembled and synthesized. With pure  $\text{Cd}_{0.5}\text{Zn}_{0.5}\text{S}$  containing  $57.0 \text{ mmol g}^{-1} \text{ h}^{-1} \text{ H}_2$  with Au added, this production increased to  $96.0 \text{ mmol g}^{-1} \text{ h}^{-1}$ . However, gold is also an expensive auxiliary. Thanks to the high cost and scope of these auxiliaries, auxiliary units that can replace precious metals will bring innovation [63].

Hinnemann et al. (2005) discovered that  $\text{MoS}_2$  improved the activity of the hydrogen generation process, indicating that it was a suitable low-cost alternative co-catalyst to platinum [64]. Many investigations have demonstrated that  $\text{MoS}_2$  may be used as a co-catalyst instead of Pt for various semiconductor photocatalysts ( $\text{TiO}_2$ ,  $\text{ZnS}$ ,  $\text{CdS}$ ,  $\text{ZnIn}_2\text{S}_4$ , and  $\text{CdZnS}$ ) [65] [1] [45]. Wei et al. (2014) produced the  $\text{MoS}_2/\text{ZnIn}_2\text{S}_4$  nanocomposite and discovered that  $\text{MoS}_2$  considerably improved hydrogen generation. As a key outcome, Pt and  $\text{MoS}_2$  were evaluated as co-catalysts, and it was discovered that  $\text{MoS}_2$  performed better under the identical circumstances [1].  $\text{MoS}_2$  has excellent electrical, optical, and catalytic capabilities, and its application with semiconductor catalysts improves  $\text{H}_2$  generation efficiency [66]. Its structure has strong intralayer covalent connections separated by a small van der Waals gap, which is critical for catalysis [67].

Zhao et al., (2016) showed that the efficiency was increased by adding MoS<sub>2</sub> and found 12.3 mmol·g<sup>-1</sup>h<sup>-1</sup> H<sub>2</sub> production with the MoS<sub>2</sub>/Cd<sub>0.5</sub>Zn<sub>0.5</sub>S photocatalyst. The reason for this is the photocatalyst with the structure MoS<sub>2</sub>/Cd<sub>0.5</sub>Zn<sub>0.5</sub>S; Photon-generated electrons are transferred from the conduction band of the Cd<sub>0.5</sub>Zn<sub>0.5</sub>S photocatalyst to the conduction band of MoS<sub>2</sub> to produce H<sub>2</sub>, and the photon-generated holes oxidize the sacrificial agents [45]. Wang et al., (2023) used 0.8% MoS<sub>2</sub>/Cd<sub>0.6</sub>Zn<sub>0.4</sub>S catalyst and the best result was found to be 13.5 mmol g<sup>-1</sup>h<sup>-1</sup>. The amount of MoS<sub>2</sub> co-catalyst in the photocatalyst has been determined as a factor affecting H<sub>2</sub> production [46]. Furthermore, MoS<sub>2</sub> is regarded a Pt alternative since it is synthesized in sheet form (2D), like the structure of graphene [68]. These 2D ultra-intense MoS<sub>2</sub> nanotubes have higher catalytic activity and higher electron mobility than bulk MoS<sub>2</sub>. According to Saadati et al. (2021), ultra-intense MoS<sub>2</sub> nanolayers have significant catalytic activity, which leads to the creation of active edge zones [69]. MoS<sub>2</sub>-based photocatalysts have demonstrated better shape, crystal structure, electrical characteristics, and durability [70]. When bulk MoS<sub>2</sub> is synthesized in 2D and the number of nanolayers is adjusted, it transitions from an indirect band gap semiconductor to a direct band gap semiconductor. The band gap value theoretically changes from 1.3 eV to 1.8 eV when bulk MoS<sub>2</sub> is converted to monolayer MoS<sub>2</sub> [2]. Based on these collected literature investigations, it was established that generating MoS<sub>2</sub> nanosheet is more favorable.

In their research, Li et al. (2021) developed a 2D/2D MoS<sub>2</sub>/Cd<sub>0.5</sub>Zn<sub>0.5</sub>S catalyst, with the greatest hydrogen generation of 15.9 mmol g<sup>-1</sup>h<sup>-1</sup> for 4.3% MoS<sub>2</sub> [71]. Yin et al. (2016) manufactured the MoS<sub>2</sub> co-catalyst as a nanosheet on the CdS nanorod photocatalyst and measured hydrogen generation at 49.8 mmol. g<sup>-1</sup>h<sup>-1</sup>. In this work, the hydrothermal technique was also employed; the autoclave was held at 220°C for 24 hours [61] [71] [72]. The catalyst's structure may be differentiated by modifying synthesis parameters such as reaction duration, temperature, and the kind and concentration of starting materials. All these characteristics influence the morphology, porosity, and particle size properties of the photocatalyst. Temperature during hydrothermal/solvothermal synthesis is another crucial element in catalyst production. To synthesize MoS<sub>2</sub> nanolayers, a temperature of 220 °C was used for 24 hours [46]. Studies conducted with Cd<sub>x</sub>Zn<sub>1-x</sub>S/MoS<sub>2</sub> are summarized in [Table 2.4](#).

**Table 2.4** Hydrogen production and efficiency values of different bare Cd<sub>x</sub>Zn<sub>1-x</sub>S/MoS<sub>2</sub> samples.

Catalyst Type	Catalyst Amount (mg)	Light Intensity (W/m <sup>2</sup> )	Hydrogen Production Amount (mmol g <sup>-1</sup> h <sup>-1</sup> )	% Quantum Efficiencies	References
Cd <sub>0.5</sub> Zn <sub>0.5</sub> S / MoS <sub>2</sub>	4	300 W Xe lamp	15.9	-	61
Cd <sub>0.6</sub> Zn <sub>0.4</sub> S / MoS <sub>2</sub>	30	300 W Xe lamp	13.5	21.81	46
Cd <sub>0.5</sub> Zn <sub>0.5</sub> S / MoS <sub>2</sub>	60	320 W/ m <sup>2</sup>	12.3	31.69	45
Cd <sub>0.5</sub> Zn <sub>0.5</sub> S / MoS <sub>2</sub>	10	300 W Xe lamp	37.2	36.3	71
Cd <sub>0.5</sub> Zn <sub>0.5</sub> S / MoS <sub>2</sub>	-	300 W Xe lamp	96.0	-	63

#### 2.4.1. Molybdenum carbides (MoC -Mo<sub>2</sub>C)

Molybdenum carbides (MoC, Mo<sub>2</sub>C) are a potential HER catalyst due to their d-band electronic structure, like platinum. However, their HER catalytic activities were not as well-performed as predicted compared to platinum. Elemental doping or material hybridization can increase their catalytic activity by modifying band topologies. A MoC-Mo<sub>2</sub>C composite powder catalyst has shown increased electrocatalytic activity, but the fundamental process is uncertain. The catalyst also runs at a low current density for less than 30 hours at room temperature [73]. However, strong Mo-H bonds cause poor hydrogen desorption, resulting in a slow H<sub>2</sub> evolution rate. As a result, it is critical to study innovative ways for tuning the electron structure of Mo<sub>2</sub>C to fast release hydrogen and increase hydrogen production rate [74].

In the literature, electrochemical experiments were often performed with MoC or Mo<sub>2</sub>C. Wei et al. (2022) produced carbon-modified phase MoC-Mo<sub>2</sub>C or MoC-Mo<sub>2</sub>C@C, MMC nanosheets on a nanorod-sized Cd<sub>0.5</sub>Zn<sub>0.5</sub>S catalyst. The inclusion of MMC considerably boosted the rate of hydrogen generation compared to the pure Cd<sub>0.5</sub>Zn<sub>0.5</sub>S catalyst. While

the pure form generates  $8.9 \text{ mmol g}^{-1} \text{ h}^{-1}$  of hydrogen, adding 1% by weight MMC increases the rate to  $68.8 \text{ mmol g}^{-1} \text{ h}^{-1}$ . This work demonstrated that the MoC-Mo<sub>2</sub>C structure may be employed for photocatalytic hydrogen generation. The quantum efficiency of 1-MMC/ZCS photocatalyst was tested using Na<sub>2</sub>S/Na<sub>2</sub>SO<sub>3</sub> as a hole sacrificial reagent and 420 nm monochromatic light, and it was 32.9% [75]. Construction of core-shell type nanostructures via linking the abundant hydrogen production catalyst Mo<sub>2</sub>C to the excellent photo absorber CdS may be the ideal combination for photocatalytic hydrogen generation. Thus, for the first time, core-shell nanorods made of a CdS core and a Mo<sub>2</sub>C-C shell were developed and produced by Yi et al. (2017). The generated CdS@Mo<sub>2</sub>C-C nanorods had a higher hydrogen production rate of  $17.24 \text{ mmol g}^{-1} \text{ h}^{-1}$  than pure CdS. This could be attributed to the unique a one-dimensional nanostructure with extensive interaction among the core and shell materials, as well as an expanded visible light absorption range [76].

In this study, its activity in hydrogen production was examined by working with two different solvents (1,3-Diaminopropane (DAP) and Ethylenediamine (EDA)). Firstly, Cd<sub>x</sub>Zn<sub>1-x</sub>S was synthesized using DAP at different x ratios (0.7/0.3 and 0.3/0.7) and MoS<sub>2</sub> was added at different mass ratios (1% and 5%). The trials of the planned catalyst were designed with an experimental design, and the impact of three distinct parameters on the generation of hydrogen were investigated (catalyst amount (mg), x ratios and MoS<sub>2</sub>%). The experimental design was made using MINITAB program and the experimental results were interpreted statistically. Another catalysts design was made using EDA. Cd<sub>0.7</sub>Zn<sub>0.3</sub>S catalyst was synthesized at different EDA/water ratios and the catalyst was synthesized in nanorod structure. MoS<sub>2</sub> was added at different mass percentages (1%, 3%, 5%, 7%, 10%, and 15%) and its effect on activity was examined. In the last part of the study, MoC-Mo<sub>2</sub>C was synthesized for the first time in the literature on the Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/MoC-Mo<sub>2</sub>C catalyst, which gave the best results, and its effect on hydrogen production was examined and interpreted by adding it in different ratios (0.5%, 1.0%, 1.5%, and 2.0%).

### 3. MATERIALS and METHODS

#### 3.1. Preparation of Samples Using 1,3-Diaminopropane (DAP)

##### 3.1.1. Materials

All the reagents were employed without additional purification. Chemicals utilized included cadmium nitrate ( $\text{Cd}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ , Merck), zinc acetate ( $\text{Zn}(\text{AC})_2 \cdot 2\text{H}_2\text{O}$ , Merck), thiourea ( $\text{NH}_2\text{CSNH}_2$ , Merck), sodium molybdate ( $\text{Na}_2\text{MoO}_4 \cdot 2\text{H}_2\text{O}$ , Alfa Aesar), and 1,3-diaminopropane (1,3-DAP, TCI EUROPE NV). The materials used in [Figure 3.1.](#) are shown.

**Figure 3.1** Chemicals used in the experiment.

##### 3.1.2. Synthesis of $\text{Cd}_x\text{Zn}_{1-x}\text{S}$ nanoparticles

$\text{Cd}_x\text{Zn}_{1-x}\text{S}$  nanoparticles were created using a solvothermal technique [76].  $\text{Cd}(\text{CH}_3\text{COO})_2 \cdot 2\text{H}_2\text{O}$  and  $\text{Zn}(\text{CH}_3\text{COO})_2 \cdot 2\text{H}_2\text{O}$  were dissolved ( $\text{Cd}/\text{Zn} = 7/3$  and  $3/7$ ) in 1,3-DAP with vigorous magnetic stirring at room temperature. Then thiourea was added three times more than the total Cd and Zn mole number. After 60 minutes of stirring, the solution was transferred to a Teflon-coated stainless-steel autoclave to be kept at  $180^\circ\text{C}$  for 24 hours. After the autoclave was naturally cooled down, the precipitate was filtered, washed several times with water, and dried overnight at  $65^\circ\text{C}$ . In [Figure 3.2.](#), the synthesis procedure is visually given.

**Figure 3.2** Images of (A) teflon-coated stainless-steel autoclave to be kept in the oven at 180°C for 24 hours, (B) solution obtained after autoclave, (C) filtration of the solution, (D) autoclave system used in the synthesis, and (E) obtained  $Cd_xZn_{1-x}S$  catalyst.

### 3.1.3. Synthesis of $Cd_xZn_{1-x}S/MoS_2$

**Figure 3.3** Images of (A) pure  $Cd_{0.3}Zn_{0.7}S$  and (B) synthesized  $Cd_{0.3}Zn_{0.7}S/5\%MoS_2$ .

To create  $Cd_xZn_{1-x}S/1\% MoS_2$  and  $Cd_xZn_{1-x}S /5\% MoS_2$  binary photocatalysts,  $Cd_xZn_{1-x}S$  nanoparticles were suspended in water and  $Na_2MoO_4 \cdot 2H_2O$  was added as a precursor. The  $MoS_2$  concentration by weight was varied. Thiourea was used as a sulfurizing agent. After 60 minutes in an ultrasonic bath, the suspension was transferred to a Teflon-coated stainless-steel autoclave and stored at  $180^\circ C$  for 24 hours. After the autoclave had naturally cooled down, the precipitate was filtered, washed several times with water, and dried overnight at  $65^\circ C$ . The results are provided as the following compositions.  $Cd_{0.7}Zn_{0.3}S$ ,  $Cd_{0.3}Zn_{0.7}S$ ,  $Cd_{0.7}Zn_{0.3}S/5\%MoS_2$ ,  $Cd_{0.7}Zn_{0.3}S/1\%MoS_2$ ,  $Cd_{0.3}Zn_{0.7}S/1\%MoS_2$ , and  $Cd_{0.3}Zn_{0.7}S/5\%MoS_2$ . [Figure 3.3A](#) has pure  $Cd_{0.3}Zn_{0.7}S$  and [Figure 3.3B](#) has images after the addition of  $MoS_2$ .

#### **3.1.4. Electrochemical Measurement**

For electrochemical measurements, it was mixed with DR Blade by mixing with enough sample ethylene glycol on the Ito glass. The conductivity was measured by voltmeter due to the lack of a conductor of the Ito glass, the conductivity was measured, and the conductive part was covered ([Figure 3.4A-D](#)). The first form of the coated samples is shown in [Figure 3.4B](#). The samples were then dried at  $50^\circ C$  in the magnetic active ([Figure 3.4C](#)). The visuals of all samples containing  $MoS_2$  are shown in [Figure 3.4D](#).

**Figure 3.4** The studies of electrochemical applications.

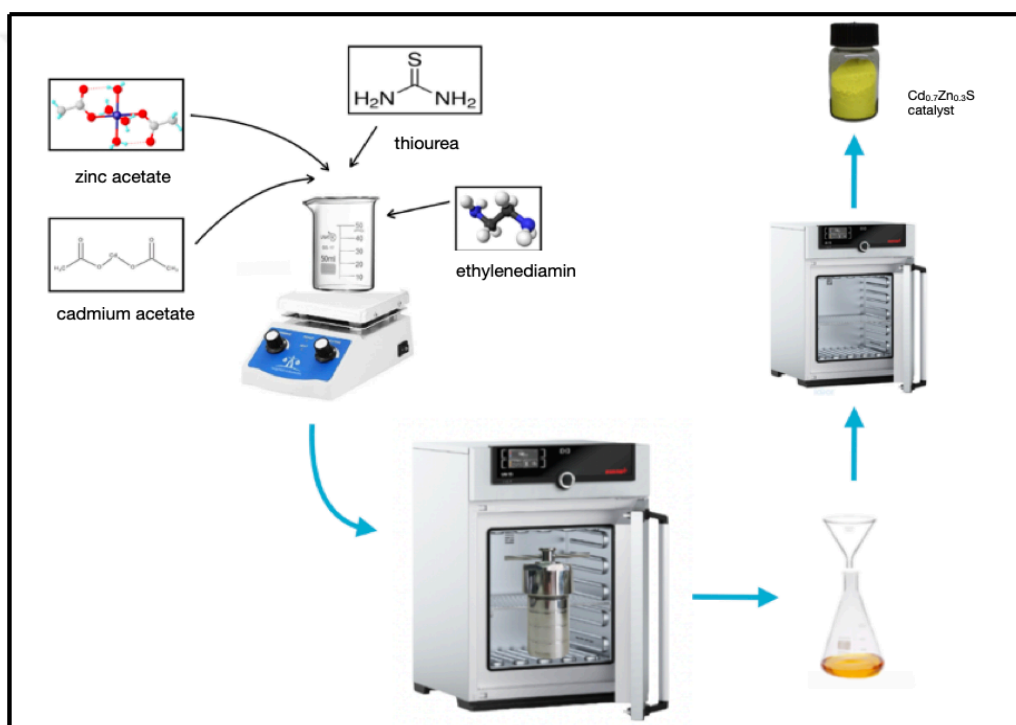

## 3.2. Preparation of Samples Using Ethylenediamine (EDA)

### 3.2.1. Materials

All the reagents were employed without additional purification. Chemicals utilized included cadmium nitrate ( $\text{Cd}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ , Merck), zinc acetate ( $\text{Zn}(\text{AC})_2 \cdot 2\text{H}_2\text{O}$ , Merck), thiourea ( $\text{NH}_2\text{CSNH}_2$ , Merck), sodium molybdate ( $\text{Na}_2\text{MoO}_4 \cdot 2\text{H}_2\text{O}$ , Merck), ethylenediamine (EDA, Sigma-Aldrich), and melamine ( $\text{C}_3\text{H}_6\text{N}_6$ , Merck).

### 3.2.2. Synthesis of $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}$ with different ratios of EDA/water.

Nanorod  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  were created using a solvothermal technique with using ethylenediamine (EDA).  $\text{Cd}(\text{CH}_3\text{COO})_2 \cdot 2\text{H}_2\text{O}$  and  $\text{Zn}(\text{CH}_3\text{COO})_2 \cdot 2\text{H}_2\text{O}$  were dissolved ( $\text{Cd}/\text{Zn} = 7/3$ ) in different EDA/water ratio with vigorous magnetic stirring at room temperature. Then thiourea was added three times more than the total Cd and Zn mole number. After 60 minutes of stirring, the solution was transferred to a Teflon-coated stainless-steel autoclave to be kept at  $180^\circ\text{C}$  for 24 hours. After the autoclave was naturally cooled down, the precipitate was filtered, washed several times with water, and dried overnight at  $65^\circ\text{C}$ . Figure 3.5. has a synthesis procedure scheme.

**Figure 3.5** Schematic representation of the synthesis procedure of  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}$  with different EDA/water ratios.

### 3.2.3. Synthesis of $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/\text{MoS}_2$

To create  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/1\% \text{ MoS}_2$ ,  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/3\% \text{ MoS}_2$ ,  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/5\% \text{ MoS}_2$ ,  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/7\% \text{ MoS}_2$ ,  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/10\% \text{ MoS}_2$ , and  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/15\% \text{ MoS}_2$  binary photocatalysts,  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}$  nanoparticles were suspended in water and  $\text{Na}_2\text{MoO}_4 \cdot 2\text{H}_2\text{O}$  was added as a precursor. The  $\text{MoS}_2$  concentration by weight was varied. Thiourea was used as a sulfurizing agent. After 60 minutes in an ultrasonic bath, the suspension was

transferred to a Teflon-coated stainless-steel autoclave and stored at 220°C for 24 hours. After the autoclave had naturally cooled down, the precipitate was filtered, washed several times with water, and dried overnight at 65°C. Figure 3.6. shows a schematic synthesis procedure to add MoS<sub>2</sub>. In Figure 3.7., the visual appearance of catalysts is given.

**Figure 3.6** Schematic procedure of synthesis of MoS<sub>2</sub> on Cd<sub>0.7</sub>Zn<sub>0.3</sub>S synthesized with hydrothermal method.

**Figure 3.7** Images of Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/MoS<sub>2</sub> catalysts synthesized with different MoS<sub>2</sub> ratios (MoS<sub>2</sub> ratio increases from left to right and MoS<sub>2</sub> synthesized alone is shown on the far left).

### 3.2.4. Synthesis of MoC-Mo<sub>2</sub>C

MoC-Mo<sub>2</sub>C nanoparticles were produced using a high-temperature calcination technique. To get a homogeneous solution, dissolve 1 g of sodium molybdate and 1.5 g of melamine in 80 mL of water and stir continuously in an 85 °C water bath. The solvent was evaporated until dry, and the resulting white powder was crushed and deposited in a quartz tube furnace. It was calcined at 800 °C for 2 hours under N<sub>2</sub> gas. The synthesized product was labeled as MoC-Mo<sub>2</sub>C [75] (Figure 3.8).

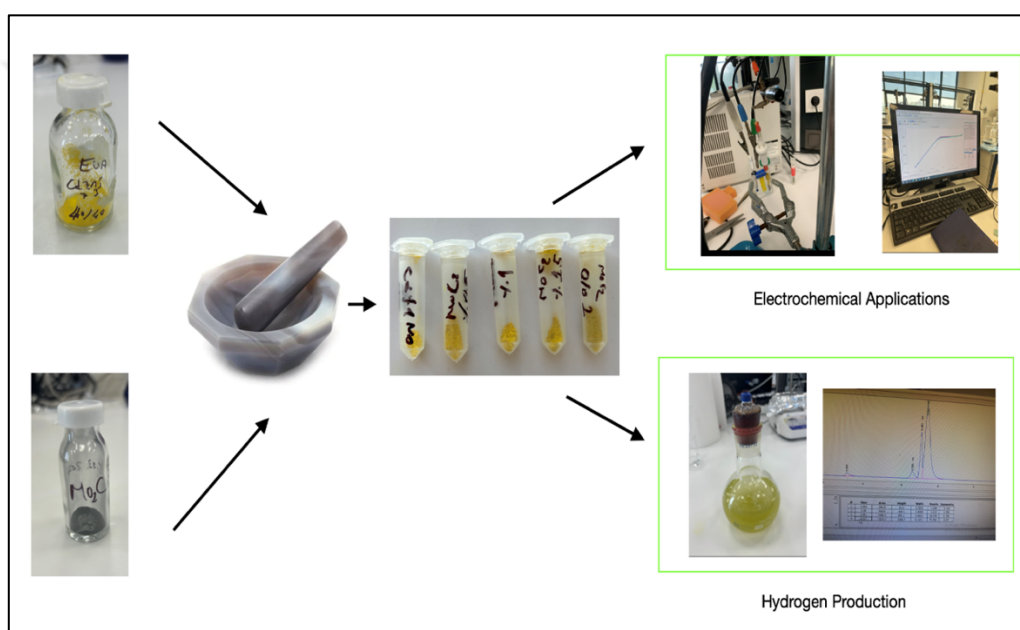

**Figure 3.8** (A) Chemical vapor deposition (CVD), (B) tubes, and (C) the picture of MoC-Mo<sub>2</sub>C.

### 3.2.5. Synthesis of Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/MoC-Mo<sub>2</sub>C

The synthesized MoC-Mo<sub>2</sub>C was added to the Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>, the best catalyst in hydrogen production and electrochemical measurements. Figure 3.10 shows the synthesis procedure. MoC-Mo<sub>2</sub>C has been added solidly on Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub> at different mass percentage rates (0.5 %, 1 %, 1.5 %, and 2 %) (Figure 3.9). First of all, the required amount of Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub> and MoC-Mo<sub>2</sub>C were weighed in the agat mortar and grinded for 1 hour. Necessary characterization and measurements were made after drying. The synthesized samples were called N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/0.5% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.5% MoC-Mo<sub>2</sub>C, and N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/2% MoC-Mo<sub>2</sub>C.

**Figure 3.9** Images of catalysts after the addition of the synthesized MoC-Mo<sub>2</sub>C.

**Figure 3.10** Synthesis procedure designed to add MoC-Mo<sub>2</sub>C on Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>.

### 3.2.6. Photocatalytic Hydrogen Production

Photocatalytic hydrogen generation reactions were carried out in a 250 mL quartz reactor. In all studies, 150 ml of 0.25 M Na<sub>2</sub>S-0.35 M Na<sub>2</sub>SO<sub>3</sub> solution were utilized. The Philips 13095 halogen lamp was used to replicate sunlight, and the distance between the photocatalyst and the light source was adjusted to achieve a light intensity of 1000 W/m<sup>2</sup>. The gas in the reactor was sampled using a gas syringe at regular intervals and examined using gas chromatography. Analysis was taken with a syringe for 5 hours and the hydrogen produced was calculated.

## 4. RESULTS AND DISCUSSION

### 4.1. Characterization Results of $\text{Cd}_x\text{Zn}_{1-x}\text{S}/\text{MoS}_2$ Synthesized Using 1,3-Diaminopropane (DAP)

#### 4.1.1. X-Ray Diffraction Analysis (XRD) Results of Samples with 1,3-Diaminopropane (DAP)

Figure 4.1. shows the XRD patterns of photocatalysts with varying Cd/Zn ratios and  $\text{MoS}_2$  concentration. When  $\text{Cd}_x\text{Zn}_{1-x}\text{S}$  samples are studied, the diffraction patterns resemble hexagonal phase CdS (JCPDS card No. 41-1049) [78]. Peaks at 25.6, 27.09, 28.85, 37.72, 44.81, 48.88, and 53.11 correspond to the (100), (002), (101), (102), (110), (103), and (102) planes, respectively [26]. As the Cd/Zn ratio increased, the displacement of the peaks altered somewhat. The shift is small because the hexagonal phase of Cd is more stable than Zn.

Figure 4.1 XRD patterns of  $\text{Cd}_x\text{Zn}_{1-x}\text{S}/\text{MoS}_2$  photocatalysts.

#### 4.1.2. Transmission Electron Microscope (TEM) Images of Samples with 1,3-Diaminopropane (DAP)

TEM analysis was performed to evaluate the microstructure and morphology. Figures 4.2. and Figure 4.3. show the TEM images and elemental mapping of the  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/1\% \text{MoS}_2$  photocatalyst, respectively. The photocatalyst exhibited an evenly dispersed nanocomposite form with a diameter of 15-35 nm and a length of 30-100 nm, resembling nanorods (Figure 4.2a-c). Figure 4.2d displays a HRTEM picture of the contact between  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}$  and  $\text{MoS}_2$ .  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}$  was detected in the (101) plane, which has a d-spacing of 0.33 nm [79], whereas  $\text{MoS}_2$  had a d-spacing of 0.28 nm in the (002) plane [26]. The absence of noticeable peaks in the XRD examination of the  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/1\% \text{MoS}_2$  and the absence of a defined lattice structure indicate that the  $\text{MoS}_2$  structure is amorphous, which contributes to increased photocatalytic activity. Figure 4.3a shows a STEM image of a specific part of the  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/1\% \text{MoS}_2$ . The photocatalyst sample's elemental mapping clearly identifies all elements, including Cd, Zn, S, and Mo, as shown in Figure 4.3b-f.

**Figure 4.2** (a, b, c) TEM images of the  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/1\% \text{MoS}_2$  nanocomposites; (d) HRTEM image of the interface between  $\text{MoS}_2$  and  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}$  in 5 nm.

**Figure 4.3** (a) STEM image of an interface; STEM image of the  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/1\% \text{MoS}_2$  nanocomposites corresponding elemental distribution of (b) mix of elements, (c) Cd, (d) Zn, (e) S and (f) Mo.

#### 4.1.3. Ultraviolet–Visible Diffuse Reflectance Spectroscopy (UV–Vis DRS) Results of Samples with 1,3-Diaminopropane (DAP)

Figure 4.4. shows the UV-vis absorption spectra of the photocatalysts, while table 4.1 presents the absorption wavelength edge and corresponding band gap values for each photocatalyst. Pure  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}$  exhibited an absorption edge at approximately 528 nm, corresponding to a 2.34 eV band gap (Figure 4.4a); pure  $\text{Cd}_{0.3}\text{Zn}_{0.7}\text{S}$  exhibited an absorption edge at approximately 522 nm, corresponding to a 2.37 eV band gap (Figure 4.4b). The band gap value rose due to the greater Zn ratio. Furthermore, adding  $\text{MoS}_2$  progressively to both  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}$  and  $\text{Cd}_{0.3}\text{Zn}_{0.7}\text{S}$  resulted in a shift across the visible spectrum. The calculated direct band gaps are given in Table 4.1.

**Figure 4.4** (a) UV-vis absorption spectra of  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}$ ,  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/1\% \text{MoS}_2$  and  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/5\% \text{MoS}_2$  and (b) UV-vis absorption spectra of  $\text{Cd}_{0.3}\text{Zn}_{0.7}\text{S}$ ,  $\text{Cd}_{0.3}\text{Zn}_{0.7}\text{S}/1\% \text{MoS}_2$  and  $\text{Cd}_{0.3}\text{Zn}_{0.7}\text{S}/5\% \text{MoS}_2$ .

**Table 4.1** UV-vis absorption wavelength edge and band gap values of photocatalysts.

Catalysts	Wavelength (nm)	Direct Band Gaps (eV)
$\text{Cd}_{0.3}\text{Zn}_{0.7}\text{S}$	522	2.37
$\text{Cd}_{0.3}\text{Zn}_{0.7}\text{S}/1\% \text{MoS}_2$	527	2.35
$\text{Cd}_{0.3}\text{Zn}_{0.7}\text{S}/5\% \text{MoS}_2$	549	2.26
$\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}$	528	2.34
$\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/1\% \text{MoS}_2$	533	2.32
$\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/5\% \text{MoS}_2$	555	2.23

#### 4.2. Design of The Experiment and Interpretation of $\text{H}_2$ Production Results Using MINITAB

The effects of photocatalytic hydrogen production were examined using the Cd/Zn ratio (0.7/0.3 and 0.3/0.7),  $\text{MoS}_2$  concentration (0, 1, and 5 w%), and photocatalyst loading (10, 25, and 50 mg). To investigate the impact of these parameters and their interactions, an experimental design was carried out using Minitab 19 statistical analysis software

[80][81]. Table 4.2. shows the 36 runs of the experiment and the findings required by this experimental design. The amount of hydrogen produced after 5 hours is given H<sub>2</sub> production rate (mmol g<sup>-1</sup> h<sup>-1</sup>).

**Table 4.2** Experimental matrix of uncoded factors and responses.

No	Cd/Zn Ratio	MoS <sub>2</sub> %	Catalyst Amount (mg)	H <sub>2</sub> Production Rate (mmol g <sup>-1</sup> h <sup>-1</sup> )

35	0.3/0.7	1	25	142
36	0.7/0.3	1	25	97

The study's hydrogen production findings were expressed mathematically as [Equation \(4.1\)](#). The parameters affecting the design are specified in the formula as subscripts (Cd/Zn=0.7/0.3=2.33, Cd/Zn=0.3/0.7=0.42; 0, 1, and 5 are MoS<sub>2</sub> loading percentages; 10, 25, and 50 are the amount of catalyst used). [Table 4.3](#) displays the linear, two-way interaction, and three-way interaction models used in the study's analysis of variance to determine the impacts of the three independent factors. P-values are used to investigate the influence of parameters on one another. Parameters with a P-value less than 0.05 have a significant influence on the study, whereas parameters with a higher P-value have a little impact [82]. The independent variables Cd/Zn ratio, catalyst amount (mg), and MoS<sub>2</sub> loading % had statistically significant ( $P < 0.05$ ) influence on the dependent variable hydrogen generation. This research revealed the importance of linear and two-way interaction models. When two-way interactions are evaluated, it can be said that Cd/Zn and catalyst quantity are major independent factors influencing the analysis because of the high f value and low p value. When each parameter was studied independently, the linear results indicated that the catalyst loading quantity was the most critical parameter, however other parameters were essential in this study. The F value of the regression model created for the experimental design in ANOVA was found to be 4.36.

$$\begin{aligned} \text{Responses (Hydrogen Production (mmol g}^{-1}\text{h}^{-1}))} &= 154.0 - 29.5*\text{Cd/Zn}_{0.42} + \\ &29.5*\text{Cd/Zn}_{2.33} - 69.3*\text{MoS}_{2.0} + 26.2*\text{MoS}_{2.1} + 43.1*\text{MoS}_{2.5} + 77.0*\text{Catalyst Amount}_{10} - \\ &10.6*\text{Catalyst Amount}_{25} - 66.5*\text{Catalyst Amount}_{50} \end{aligned} \quad (4.1)$$

**Table 4.3** Analysis of variance.

Figure 4.5. shows the pareto chart of the hydrogen generation outcomes changing with independent parameters. After analyzing every parameter separately and through interaction in the Pareto chart, the critical t-value for the degree of freedom was determined to be 2.101 with a 95% confidence level and a 0.05 alpha value. When the parameters were examined, the amount of catalyst (mg) was found to be the most important parameter affecting it, and in decreasing order, MoS<sub>2</sub> loading percentage, Cd/Zn, catalyst amount (mg) with Cd/Zn etc. affects the parameters. The MoS<sub>2</sub> loading percentage can be useful for optimizing hydrogen generation because it significantly affects the results on itself. From the Pareto chart, the parameter that has the lowest

impact on the 2-way interaction's hydrogen production is the percentage of MoS<sub>2</sub> loading with Cd/Zn. Interaction graphs for the components involved in hydrogen generation are displayed in Figure 4.6. An important criterion is how the various components interact with one another to influence the optimization research on hydrogen generation. Interaction graphs can be used to examine each factor's impact. When the catalyst amount (mg) and MoS<sub>2</sub> loading percentage were compared, it was discovered that using catalysts of 25 and 50 mg improved the results of hydrogen production by increasing the MoS<sub>2</sub> loading percentage, while using catalysts of 10 mg significantly decreased the amount of hydrogen produced, from 1% to 5%. Moreover, increased hydrogen production was seen by increasing the Cd/Zn ratio and the MoS<sub>2</sub> loading percentage, regardless of the catalyst amount. The 10 mg sample showed a significant increase in hydrogen production when the Cd/Zn ratio was compared to the catalyst amount (mg), but not in the 25 or 50 mg tests. These data indicate that the Cd<sub>0.7</sub>Zn<sub>0.3</sub>S catalyst will produce the greatest results in the 10 mg research; nevertheless, the interaction graph indicates that the catalyst performs better when the MoS<sub>2</sub> loading percentage increases to 1%.

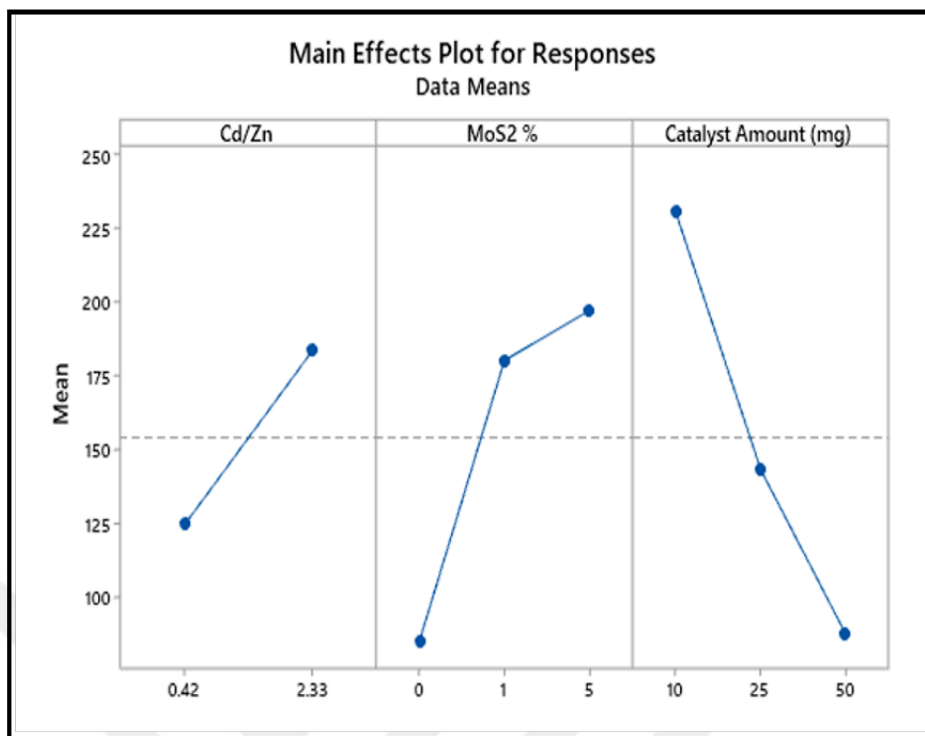

**Figure 4.5** Pareto plot of independent variables affecting hydrogen production ( $\text{mmol g}^{-1} \text{h}^{-1}$ ).

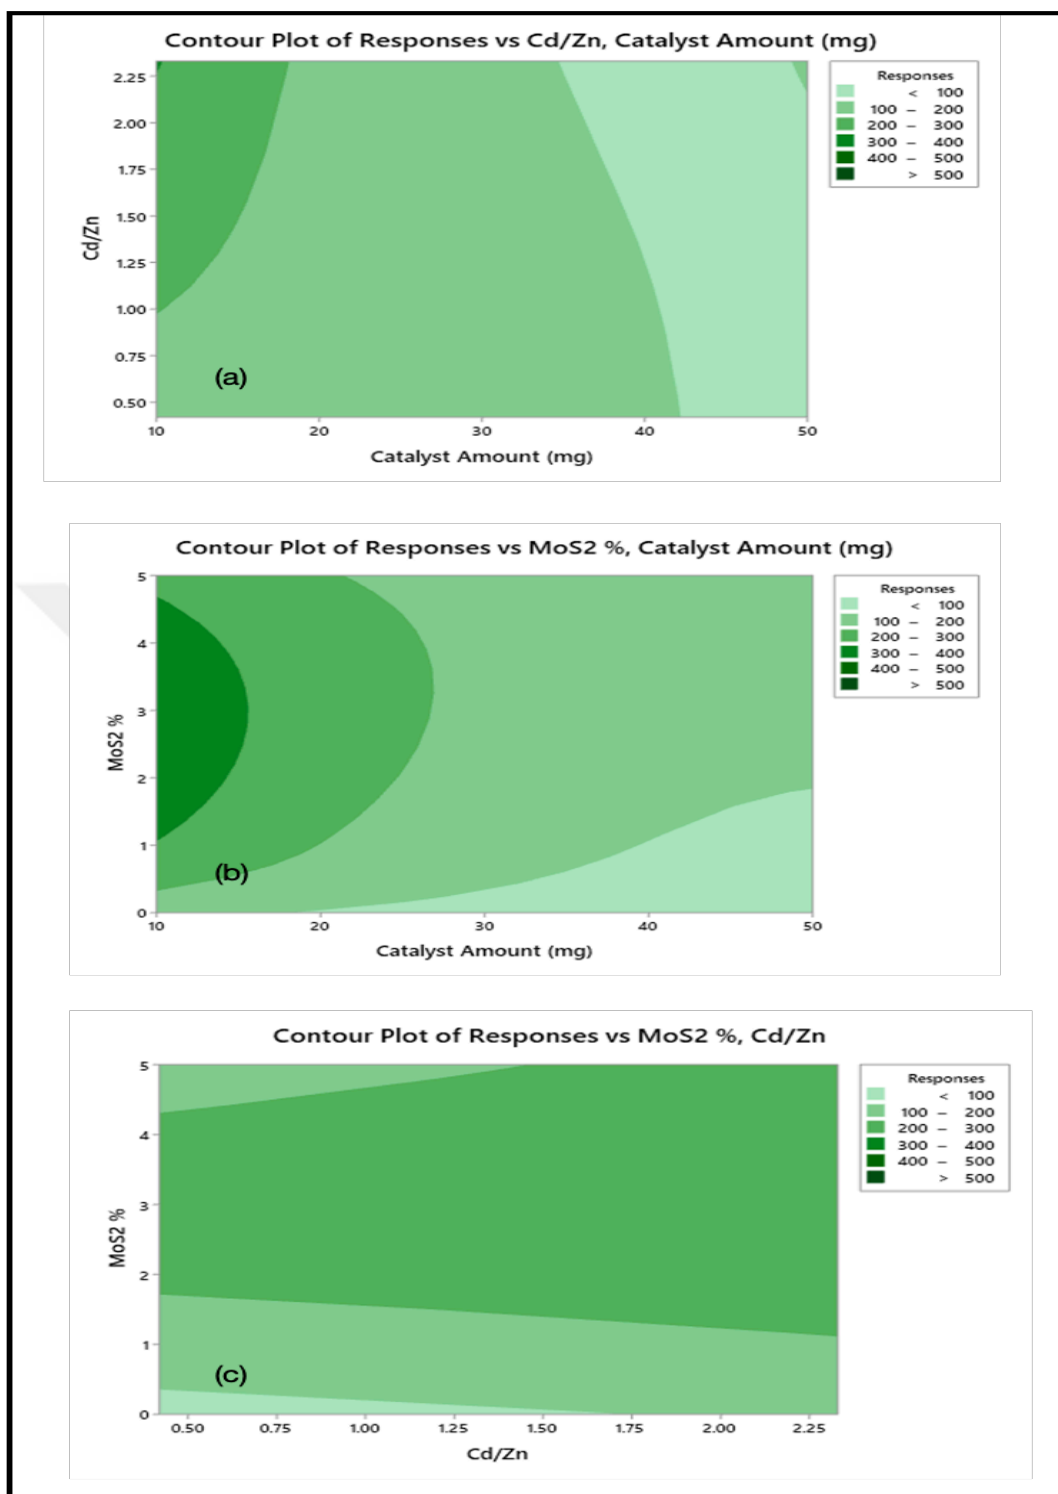

**Figure 4.6** Interaction plots of the three independent parameters for hydrogen generation.

**Figure 4.7.** shows the graphs used to determine the factor with the least impact. The main effect graph makes it easy to see how each factor affects the other. The reference line is shown in the visuals as a gray dashed line. A significant decrease in the catalyst quantity (mg) curve occurs during component evaluation. Because of its substantial effect, more research on the amount of catalyst (mg) may be undertaken. Consequently, increasing the amount of catalyst (mg) reduces hydrogen generation. Higher Cd/Zn ratios led to increased production of hydrogen ( $\text{mmol g}^{-1} \text{h}^{-1}$ ). Hydrogen production increased significantly from no  $\text{MoS}_2$  to 1%  $\text{MoS}_2$ , but only modestly from 1% to 5%  $\text{MoS}_2$ , when the  $\text{MoS}_2$  loading percentage was taken into consideration. Consequently, altering any parameter has a significant impact on the results. On the other hand, while increasing  $\text{MoS}_2$  % and Cd/Zn increased hydrogen generation, increasing catalyst amount (mg) significantly decreased it. It is simpler to understand the consequences of each parameter with the help of this model graph.

**Figure 4.7** Main effect plots.

The contours show the impact of maintaining one component constant while changing the other two on hydrogen production responses ( $\text{mmol g}^{-1} \text{h}^{-1}$ ). The green color contoured as the response color shows that the reaction rises from light to dark green. When the findings are studied independently of  $\text{MoS}_2\%$ , it is projected that hydrogen production responses would rise when the catalyst amount (mg) is reduced, and the cadmium zinc ratio is raised (Figure 4.8a). When seen independently of the cadmium-zinc ratio, the color seems to darken, indicating better responsiveness as the amount of catalyst utilized decreases. With this reduction, the  $\text{MoS}_2$  loading percentage offers better outcomes when used at typical levels of 1% to 5%. Figure 4.8b demonstrates that employing 3%  $\text{MoS}_2$  loading in the research might yield better results. Unlike other graphs, this contour graph produced positive outcomes in selecting the most effective aspects for improving the work. The study examines hydrogen generation independent of the amount of catalyst. Figure 4.8c depicts the answers in  $\text{mmol/h}$  and increasing Cd/Zn and  $\text{MoS}_2\%$  yields better results. However, larger  $\text{MoS}_2$  loading percentages and Cd/Zn ratios cannot be entirely predicted. The contour plot results correspond with the interpretations found in other graphs (interaction and main effects plots). Furthermore, the capacity to forecast the progression of the study using these graphs sets it apart from other graphs.

**Figure 4.8** Contour graphs of the effect of (a) Cd/Zn and catalyst amount (mg), (b) MoS<sub>2</sub> % and catalyst amount (mg), (c) MoS<sub>2</sub> % and Cd/Zn on hydrogen production (mmol g<sup>-1</sup> h<sup>-1</sup>).

Surface curves showing the interaction of the change of independent parameters with the response in three dimensions, prepared by making use of the experimental design created using Full Factorial Design, are given in Figure 4.10. While drawing these curves, the effect of changing two parameters on the responses is examined while the other parameter is kept constant. Figure 4.10a illustrates the hydrogen production ( $\text{mmol g}^{-1} \text{h}^{-1}$ ) versus the levels of catalyst amount (mg) and  $\text{MoS}_2$  %. Like the two-dimensional contour graph, better responses were obtained at lower catalyst amounts and in the 1% to 5%  $\text{MoS}_2$  loading range. In Figure 4.10b, the effect of catalyst amount (mg) and Cd/Zn on the answers is examined in 3D. However, no effective results were observed from the 3D graph as compared to the 2D graph (Figure 4.8a). It can be said that the answers are slightly better at low catalyst amounts and high Cd/Zn. It can be said that a good analysis can be made when these two graphs are examined together. When Figure 4.10c was examined, similar results were seen with the 2D graph (Figure 4.8c). It is seen that the effect of adding  $\text{MoS}_2$  % at low Cd/Zn levels is low. Increasing both factors have a positive effect on the responses. The normal probability plot of the responses is given in Figure 4.9. The normal probability plot is a graphical tool for observing the normal distribution of data. The p-value and associated AD statistic for the accuracy of the distribution are also provided in the graph.

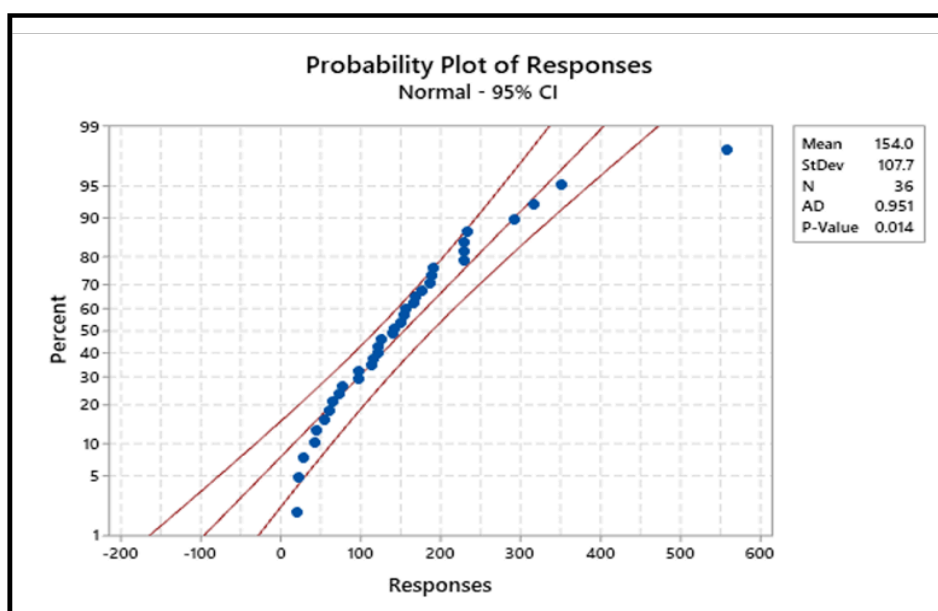

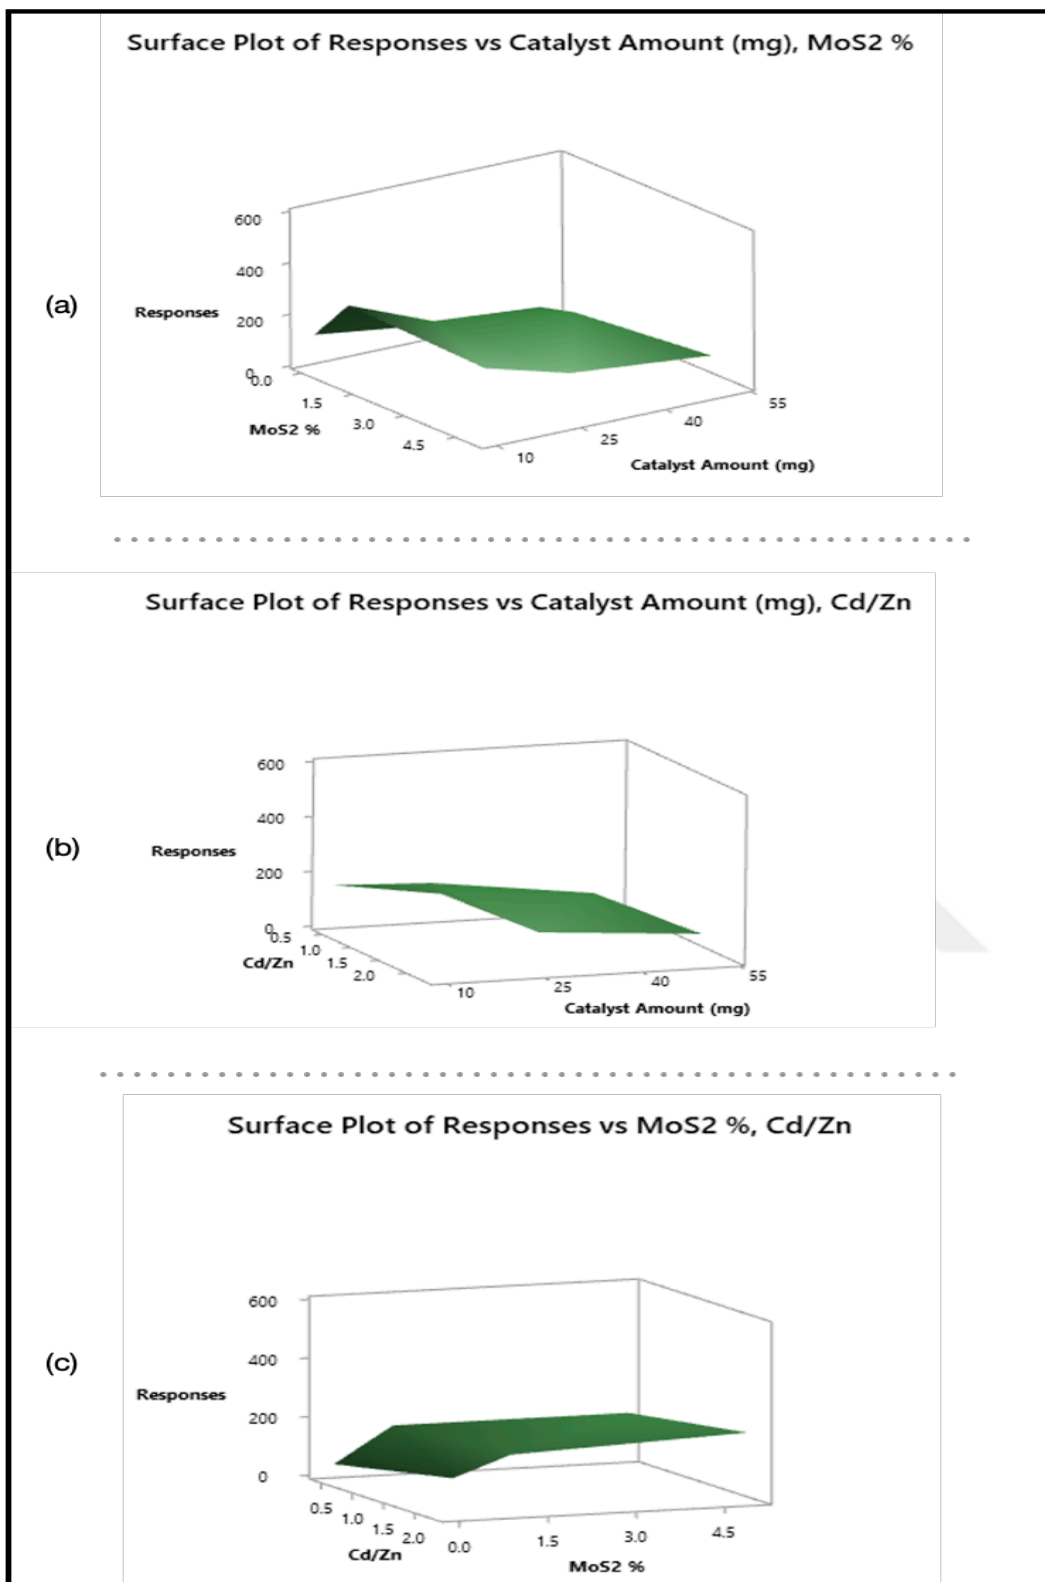

Figure 4.9 Normal probability plot.

**Figure 4.10** 3D interaction effect plot of the effect of independent factors (a) catalyst amount and MoS<sub>2</sub> %, (b) catalyst amount and Cd/Zn, (c) MoS<sub>2</sub> % and Cd/Zn on hydrogen production ( $\text{mmol g}^{-1} \text{h}^{-1}$ ).

### 4.3. Characterization Results of Nanorod $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/\text{MoS}_2$ Catalyst Synthesized Using Ethylenediamine (EDA)

#### 4.3.1. SEM Images of Nanorod $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}$ Catalyst with EDA

**Figure 4.11** SEM images of the  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/1\% \text{MoS}_2$  nanocomposites with using 40 ml EDA- 40 ml water.

In the synthesis procedure, synthesis was performed with a total of 80 ml of solvent. Experiments were carried out by changing the solution ratio used (EDA/water). In the example shown in Figure 4.11., 40 ml EDA and 40 ml water were used. In Figure 4.11a, SEM analysis was carried out with 1 micrometer and 20000 times magnification. It can be seen that the catalyst is in nanorod form, distributed homogeneously and without agglomeration. In Figure 4.11b, SEM analysis was carried out at 500 nanometers and 50000 times magnification. It has been clearly shown that the catalyst is in the form of nanorods. In the example shown in Figure 4.12., 60 ml EDA and 20 ml water were used. In Figure 4.12a, SEM analysis was carried out with 1 micrometer and 20000 times magnification. It has been shown that the catalyst approaches the rod form but is not fully synthesized as nanorods. The catalyst is in lump form. In Figure 4.12b, SEM analysis was carried out at 500 nanometers and 50000 times magnification. In the example shown in Figure 4.13., 80 ml EDA was used. In Figure 4.13a, SEM analysis was carried out with 1 micrometer and 20000 times magnification. The catalyst is clustered and does not have a specific shape. In Figure 4.13b, SEM analysis was carried out at 500 nanometers and 50000 times magnification [23][47][51].

**Figure 4.12** SEM images of the  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/1\% \text{MoS}_2$  nanocomposites with using 60 ml EDA- 20 ml water.

**Figure 4.13** SEM images of the Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub> nanocomposites with using 80 ml EDA.

#### 4.3.2. UV-Vis DRS Results of Nanorod Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/ MoS<sub>2</sub> Catalyst

The optical characteristics and band gap of the materials were investigated using UV-Vis diffuse reflectance spectroscopy (UV-Vis DRS). In diffuse reflectance spectroscopy, the device analyzes diffusely reflected light. The system under investigation consists of a substrate coated with a substance of interest that is irradiated with diffuse monochromatic radiation. The Tauc-plots (plot of  $h\nu f(R)$  vs. photon energy ( $h\nu$ )) used for calculating the direct band gap values were obtained from reflectance measurements by converting the Kubelka-Munk function (Equation 4.2). K and S represent the K-M absorption and scattering coefficients, respectively [82] [83].

$$f(R) = \frac{K}{S} = \frac{(1 - R)^2}{2R} \quad (4.2)$$

In Figure 4.15., UV-vis absorption spectra of N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/3% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/5% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/7% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/10% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/15% MoS<sub>2</sub> and MoS<sub>2</sub> are also shown. In Figure 4.14., the Cd<sub>0.7</sub>Zn<sub>0.3</sub>S synthesized as nanorods and the Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub> catalyst with the highest hydrogen production rate (mmol g<sup>-1</sup> h<sup>-1</sup>) are drawn. It was observed that with the addition of MoS<sub>2</sub>, the wavelength (nm) increased, and the direct band gap (eV) decreased.

Estimated direct band gap energies ( $E_g$ ) as a function of photon energy  $[ah\nu]^2$  based on the Kubelka-Munk function were calculated [85]. Additionally, in Table 4.4., the wavelengths (nm) and calculated direct band gaps (eV) of all catalysts synthesized by adding  $\text{MoS}_2$  are given. The direct band gaps were 2.37 eV, 2.36 eV, 2.35 eV, 2.36 eV, 2.35, 2.34, and 2.33 eV, corresponding to  $\text{N-Cd}_{0.7}\text{Zn}_{0.3}\text{S}$ ,  $\text{N-Cd}_{0.7}\text{Zn}_{0.3}\text{S}/1\% \text{MoS}_2$ ,  $\text{N-Cd}_{0.7}\text{Zn}_{0.3}\text{S}/3\% \text{MoS}_2$ ,  $\text{N-Cd}_{0.7}\text{Zn}_{0.3}\text{S}/5\% \text{MoS}_2$ ,  $\text{N-Cd}_{0.7}\text{Zn}_{0.3}\text{S}/7\% \text{MoS}_2$ ,  $\text{N-Cd}_{0.7}\text{Zn}_{0.3}\text{S}/10\% \text{MoS}_2$ ,  $\text{N-Cd}_{0.7}\text{Zn}_{0.3}\text{S}/15\% \text{MoS}_2$ , respectively. The band gap decreased in samples with  $\text{MoS}_2$  added; this can be explained by the fact that the charge transfer between pure  $\text{N-Cd}_{0.7}\text{Zn}_{0.3}\text{S}$  and added  $\text{MoS}_2$  results in a lower energy transition.

**Figure 4.14** UV-DRS absorption spectra of nanorod  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}$  -nanorod  $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/1\% \text{MoS}_2$ .

**Figure 4.15** UV-DRS absorption spectra of N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/3% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/5% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/7% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/10% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/15% MoS<sub>2</sub> and MoS<sub>2</sub>.

**Table 4.4** UV-vis absorption wavelength edge and band gap values of nanorod photocatalysts.

Catalysts	Wavelength (nm)	Direct Band Gaps (eV)
N-Cd <sub>0.7</sub> Zn <sub>0.3</sub> S	522	2.37
N-Cd <sub>0.7</sub> Zn <sub>0.3</sub> S/1% MoS <sub>2</sub>	524	2.36
N-Cd <sub>0.7</sub> Zn <sub>0.3</sub> S/3% MoS <sub>2</sub>	526	2.35
N-Cd <sub>0.7</sub> Zn <sub>0.3</sub> S/5% MoS <sub>2</sub>	525	2.36
N-Cd <sub>0.7</sub> Zn <sub>0.3</sub> S/7% MoS <sub>2</sub>	526	2.35
N-Cd <sub>0.7</sub> Zn <sub>0.3</sub> S/10% MoS <sub>2</sub>	530	2.34
N-Cd <sub>0.7</sub> Zn <sub>0.3</sub> S/15% MoS <sub>2</sub>	531	2.33

#### 4.4. Photocatalytic Hydrogen Evolution of Nanorod Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/MoS<sub>2</sub> Catalyst

Photocatalysts produced in the form of nanorods were tested for photocatalytic activity under visible light using Na<sub>2</sub>S/Na<sub>2</sub>SO<sub>3</sub> (0.35 M/0.25 M) as a sacrificial agent. Figure 4.16. depicts the H<sub>2</sub> generation rates, whereas Figure 4.17. depicts the time dependent H<sub>2</sub> evolution of N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S following addition of different MoS<sub>2</sub> concentrations. The photocatalytic performance was compared by adding MoS<sub>2</sub>. N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub> produced H<sub>2</sub> at a rate of 131.8 mmol g<sup>-1</sup> h<sup>-1</sup>, 3.5 times more than N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S. Increasing the quantity of MoS<sub>2</sub> resulted in a reduction in H<sub>2</sub> production rates because MoS<sub>2</sub> inhibited light absorption. N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub> was chosen as the greatest hydrogen-yielding catalyst for use in the MoC-Mo<sub>2</sub>C addition tests. As shown in Figure 4.17., the experiment continued 5 hours, with analysis performed every hour. The experimental results reveal that hydrogen generation rises hourly. Furthermore, the addition of MoS<sub>2</sub> caused an increase in the rate of hydrogen generation in all samples.

**Figure 4.16** Photocatalytic H<sub>2</sub> production rates of N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/3% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/5% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/7% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/10% MoS<sub>2</sub>, and N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/15% MoS<sub>2</sub> samples.

**Figure 4.17** Time-dependent H<sub>2</sub> production activities of N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/3% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/5% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/7% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/10% MoS<sub>2</sub>, and N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/15% MoS<sub>2</sub> samples.

#### 4.5. Electrochemical Applications of Nanorod Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/MoS<sub>2</sub> Catalyst

Chronoamperometry was used to assess the catalyst's stability throughout time that it was being investigated electrochemically (Figure 4.18.). The relationship between time and current produced by photogenerated electrons was examined. Chronoamperometry study was done on all photocatalysts at a potential of 0 V. Table 4.5. shows the photocurrent responses derived from the synthesized photocatalysts. According to these results, the N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub> photocatalyst produced the best photocurrent result. Compared to pure N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S, the photocurrent increased by adding of 1% MoS<sub>2</sub>. This demonstrates that heterojunctions considerably enhance the transmission of photogenerated charges [86]. This finding is supported by hydrogen production rate results. The inclusion of 10% and 15% MoS<sub>2</sub> results in lower photocurrent values compared to pure N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S. The

findings obtained were shown to be higher than the study conducted with the same type of catalyst [87].

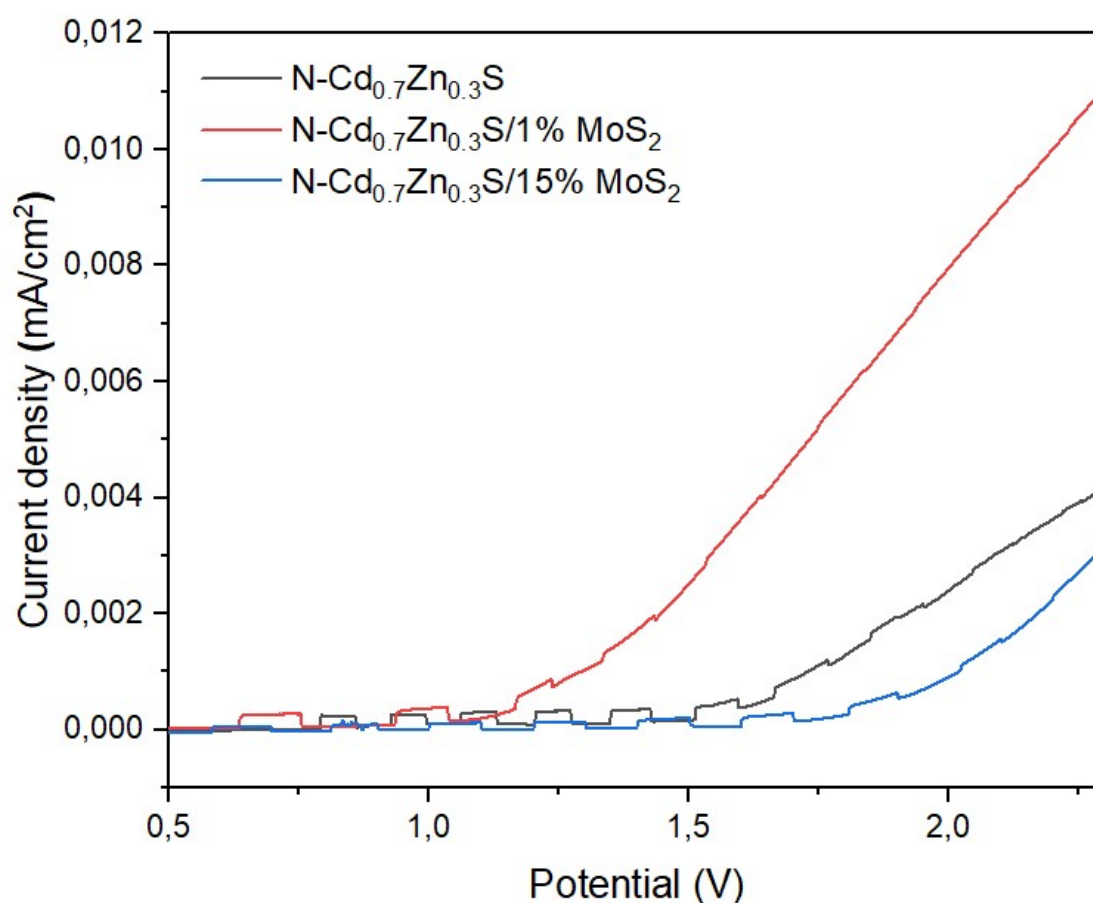

**Figure 4.18** Transient photo current curves of N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/3% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/5% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/7% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/10% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/15% MoS<sub>2</sub> samples.

**Table 4.5** Photo-current response of the synthesized catalysts.

Catalysts	Photocurrent Response (µA/cm <sup>2</sup> )
N-Cd <sub>0.7</sub> Zn <sub>0.3</sub> S	82
N-Cd <sub>0.7</sub> Zn <sub>0.3</sub> S/1% MoS <sub>2</sub>	318
N-Cd <sub>0.7</sub> Zn <sub>0.3</sub> S/3% MoS <sub>2</sub>	225
N-Cd <sub>0.7</sub> Zn <sub>0.3</sub> S/5% MoS <sub>2</sub>	278
N-Cd <sub>0.7</sub> Zn <sub>0.3</sub> S/7% MoS <sub>2</sub>	212
N-Cd <sub>0.7</sub> Zn <sub>0.3</sub> S/10% MoS <sub>2</sub>	35
N-Cd <sub>0.7</sub> Zn <sub>0.3</sub> S/15% MoS <sub>2</sub>	120

Linear Sweep Voltammetry (LSV) was used on all catalysts coated with ITO. LSV analysis was carried out in visible light. Figure 4.19. shows the resultant photocurrent response. The figure displays three distinct sample findings; pure N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub> loaded catalyst gave the best hydrogen results and N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/15% MoS<sub>2</sub> maximum MoS<sub>2</sub> loaded catalyst. The results show that photocatalysts' visible light spectrum are active. It has been demonstrated that photocurrent rises depending on whether the light is turned off or on. Studies have also shown that the addition of MoS<sub>2</sub> suppresses electron-hole recombination while increasing photocatalytic activity in the visible band. The findings are congruent with the chronoamperometry results.

**Figure 4.19** LSV of N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/3% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/5% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/7% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/10% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/15% MoS<sub>2</sub> samples.

## 4.6. Characterization Results of Nanorod $\text{Cd}_{0.7}\text{Zn}_{0.3}\text{S}/1\% \text{ MoS}_2/ \text{ MoC-Mo}_2\text{C}$ Catalyst

### 4.6.1. X-Ray Diffraction Analysis (XRD) Results of $\text{MoC-Mo}_2\text{C}$

Figure 4.20. shows the XRD patterns of the synthesized  $\text{MoC-Mo}_2\text{C}$ . XRD analysis was used to study the synthesized sample's structure and phase advancement. As shown in Figure 4.20., the sample's XRD pattern indicates the development of  $\text{MoC}$  (ICDD card no. 03-065-6664) and  $\text{Mo}_2\text{C}$  (ICDD card no. 00-035-0787) phases in the manufactured powder sample [88]. As demonstrated in the experiments, XRD examination revealed no unsynthesized C or Mo peaks. This suggests that the intended  $\text{MoC-Mo}_2\text{S}$  structure was synthesized pure [89]. In this study using CVD,  $\text{MoC-Mo}_2\text{S}$  was synthesized and then its effect on hydrogen production was studied by adding it in different mass percentages to the  $\text{N-Cd}_{0.7}\text{Zn}_{0.3}\text{S}/1\% \text{ MoS}_2$  catalyst, which gives the best hydrogen production rate ( $\text{mmol g}^{-1} \text{ h}^{-1}$ ) and shows good results in electrochemical applications.

Figure 4.20 XRD patterns of  $\text{MoC-Mo}_2\text{C}$ .

#### 4.6.2. UV-Vis DRS Results of N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/MoC-Mo<sub>2</sub>C

UV-Vis DRS measurements were made for MoC-Mo<sub>2</sub>C and 4 samples to which MoC-Mo<sub>2</sub>C was added (Figure 4.21.). In Figure 4.22., the N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub> catalyst with the highest hydrogen production rate (mmol g<sup>-1</sup> h<sup>-1</sup>) and the N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.0% MoC-Mo<sub>2</sub>C catalyst with the most efficient hydrogen production by adding MoC-Mo<sub>2</sub>C are drawn. It has been shown that the band gaps decrease with the addition of MoC-Mo<sub>2</sub>C. This type of characterization also confirms the synthesis of the catalyst. Calculated band gaps in Table 4.6. are shown below. The direct band gaps were 2.36 eV, 2.36 eV, 2.33 eV, 2.32, and 2.31 eV, corresponding to N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/0.5% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.0% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.5% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/2.0% MoC-Mo<sub>2</sub>, respectively.

**Figure 4.21** UV-DRS absorption spectra of N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/0.5% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.0% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.5% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/2.0% MoC-Mo<sub>2</sub>C and MoC-Mo<sub>2</sub>C.

**Figure 4.22** UV-DRS absorption spectra of N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub> and N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.0% MoC-Mo<sub>2</sub>C.

**Table 4.6** UV-vis absorption wavelength edge and band gap values.

Catalysts	Wavelength (nm)	Direct Band Gaps (eV)
N-Cd <sub>0.7</sub> Zn <sub>0.3</sub> S/1% MoS <sub>2</sub>	524	2.36
N-Cd <sub>0.7</sub> Zn <sub>0.3</sub> S/1% MoS <sub>2</sub> /0.5% MoC-Mo <sub>2</sub> C	525	2.36
N-Cd <sub>0.7</sub> Zn <sub>0.3</sub> S/1% MoS <sub>2</sub> /1.0% MoC-Mo <sub>2</sub> C	532	2.33
N-Cd <sub>0.7</sub> Zn <sub>0.3</sub> S/1% MoS <sub>2</sub> /1.5% MoC-Mo <sub>2</sub> C	534	2.32
N-Cd <sub>0.7</sub> Zn <sub>0.3</sub> S/1% MoS <sub>2</sub> /2.0% MoC-Mo <sub>2</sub> C	536	2.31

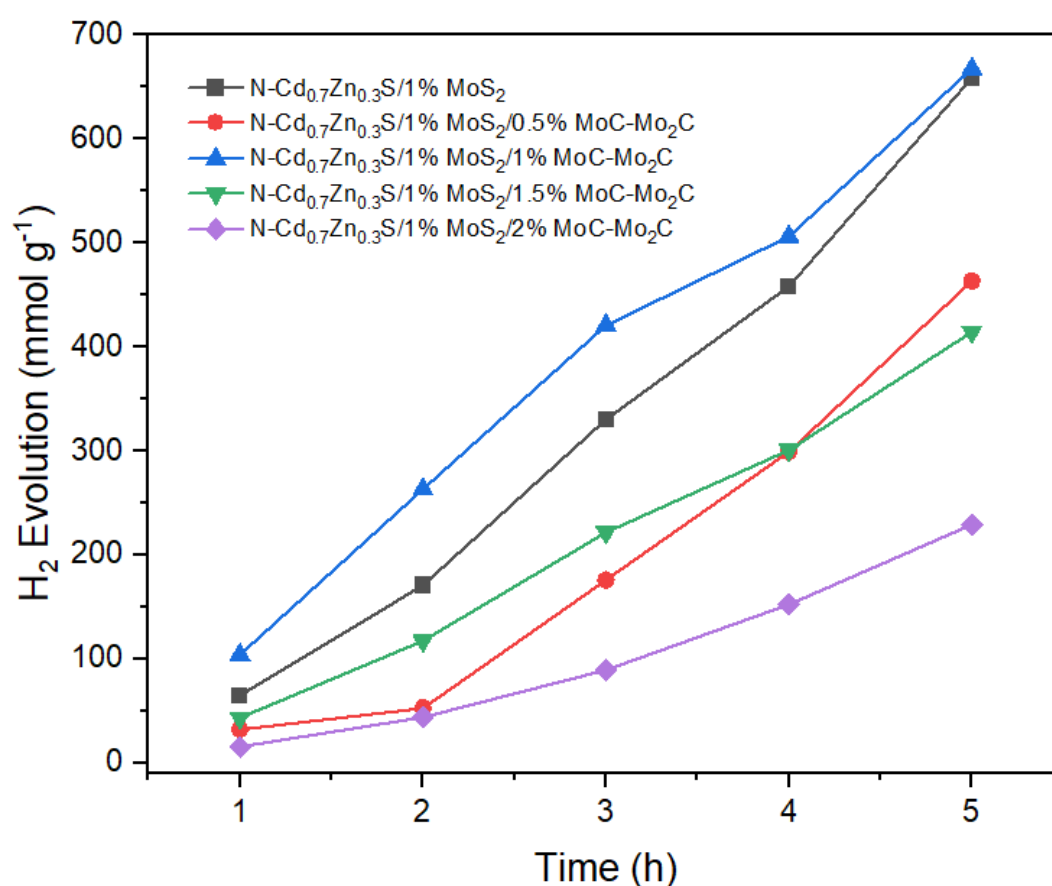

#### 4.7. Photocatalytic Hydrogen Evolution of N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/MoC-Mo<sub>2</sub>C

**Figure 4.23** Photocatalytic H<sub>2</sub> production rates of N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/0.5% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.0% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.5% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/2.0% MoC-Mo<sub>2</sub>C samples.

The catalysts, whose activity was examined by adding MoC-Mo<sub>2</sub>C, were tested for photocatalytic activity under visible light, using Na<sub>2</sub>S/Na<sub>2</sub>SO<sub>3</sub> (0.35 M/0.25 M) as a sacrificial agent, at a constant weight of 10 mg and a light intensity of 1000 W/m<sup>2</sup>. [Figure 4.23](#) shows the H<sub>2</sub> production rates, and [Figure 4.24](#) shows the time-dependent H<sub>2</sub> evolution of N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub> after adding different MoC-Mo<sub>2</sub>C mass percentage. The photocatalytic performance was compared by adding MoC-Mo<sub>2</sub>C. N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub> produced hydrogen at a rate of 131.8 mmol g<sup>-1</sup> h<sup>-1</sup>, while N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.0% MoC-Mo<sub>2</sub>C produced 133.5 mmol g<sup>-1</sup> h<sup>-1</sup>. It has been shown that hydrogen production decreases with the addition of 0.5%, 1.5% and 2.0% MoC-Mo<sub>2</sub>C. These results are supported by electrochemical measurements and UV-DRS results. In studies conducted with MoC-Mo<sub>2</sub>C, low amounts were added by mass because it prevents light absorption [75][76]. It can be said that this is because the excessive amount of MoC-

Mo<sub>2</sub>C co-catalyst on the N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub> surface and the strong light absorption capacity of black MoC-Mo<sub>2</sub>C inhibits the light absorption of N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub> catalyst, and as a result, the hydrogen evolution rate for 1.5% and 2% MoC-Mo<sub>2</sub>C decreases. In this study, the optimum MoC-Mo<sub>2</sub>C percentage was found to be 1.0%. As shown in Figure 4.24., the experiment continued for 5 hours, with analysis taken every hour. Experimental results revealed that hydrogen production increased hourly. In addition, the addition of MoC-Mo<sub>2</sub>C caused an hourly increase in all samples, but the sample that gave higher hydrogen production than its best and purest form was N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.0% MoC-Mo<sub>2</sub>C.

**Figure 4.24** Time-dependent H<sub>2</sub> production activities of N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/0.5% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.0% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.5% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/2.0% MoC-Mo<sub>2</sub>C samples.

#### 4.8. Electrochemical Applications of N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/MoC-Mo<sub>2</sub>C

**Figure 4.25** Transient photo current curves of N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/0.5% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.0% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.5% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/2.0% MoC-Mo<sub>2</sub>C samples.

Chronoamperometry was performed to evaluate the catalyst's stability during electrochemical testing (Figure 4.25.). The connection between time and current created by photogenerated electrons was investigated. All photocatalysts were subjected to a chronoamperometry examination at a potential of 0 V. According to these conclusions, the N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.0% MoC-Mo<sub>2</sub>C photocatalyst provided the highest photocurrent value. The photocurrent generation of the N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/0.5% MoC-Mo<sub>2</sub>C catalyst was lower than that of the N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.0% MoC-Mo<sub>2</sub>C catalyst, as well as 1.5% and 2.0% MoC-Mo<sub>2</sub>C. The graph shows that photocurrent drops with the addition of MoC-Mo<sub>2</sub>C. This observation is corroborated by the hydrogen generation rate.

MoC-Mo<sub>2</sub>C added samples were coated on ITO, and LSV was utilized in visible light. Photocurrent responses were measured in four samples: N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/0.5% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.0% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.5% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/2.0% MoC-Mo<sub>2</sub>C (Figure 4.26.). The results reveal that the photocatalysts created by adding MoC-Mo<sub>2</sub>C are active in the visible light spectrum. It has been demonstrated that the photocurrent varies depending on whether the light is turned off or on. Studies have also demonstrated that the addition of MoC-Mo<sub>2</sub>C increases photocatalytic activity in the visible range while suppressing electron-hole recombination. The results were found to be similar with the chronoamperometry findings.

**Figure 4.26** LSV of N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/0.5% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.0% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.5% MoC-Mo<sub>2</sub>C, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/2.0% MoC-Mo<sub>2</sub>C samples.

## 5. CONCLUSION

In this study, photocatalyst synthesis and optimization were studied to increase the activity in photocatalytic H<sub>2</sub> production. First, photocatalyst synthesis conditions were optimized in terms of H<sub>2</sub> amount produced using Full Factorial Design by Minitab 19. Cadmium zinc sulfide (Cd<sub>x</sub>Zn<sub>1-x</sub>S) photocatalyst was studied because CdS has fast electron-hole recombination, so the Cd<sub>x</sub>Zn<sub>1-x</sub>S structure was used to increase the activity. As the first synthesis method, DAP, which is not used in the literature before, was preferred and Cd<sub>x</sub>Zn<sub>1-x</sub>S photocatalysts were synthesized by solvothermal method in DAP. The important parameters for the amount of produced H<sub>2</sub> are the change in x value or namely Cd/Zn ratio, the amount of catalyst used in the photocatalytic H<sub>2</sub> production reaction (mg) and the MoS<sub>2</sub>% aimed to be added to the Cd<sub>x</sub>Zn<sub>1-x</sub>S catalyst. Cd<sub>0.7</sub>Zn<sub>0.3</sub>S and Cd<sub>0.3</sub>Zn<sub>0.7</sub>S were studied for x value; 10, 25, and 50 mg were selected as amounts of catalyst used in the photocatalytic H<sub>2</sub> production; and 1% and 5% were selected for MoS<sub>2</sub> addition. In the statistical interpretations of ANOVA, the Catalyst Amount was found to be significant for the single factor effect, and the Cd/Zn\*Catalyst Amount was found to be significant for double interactions because the p value was below 0.05. As a result, these parameters were determined as the main factors affecting H<sub>2</sub> production. Graphically, the effects of pareto charts, interaction plots, main effect plots, contour graphs and 3D interaction effect plots are discussed and interpreted. For the highest hydrogen producing catalyst, a production rate of 560 mmol g<sup>-1</sup> h<sup>-1</sup> H<sub>2</sub> was found by using 10 mg of Cd<sub>0.7</sub>Zn<sub>0.3</sub>S sample and adding 1% MoS<sub>2</sub>. XRD, TEM, HRTEM, STEM, and UV-Vis DRS were used for the characterization of the photocatalysts. It was observed that the peaks in XRD did not change with the change in MoS<sub>2</sub>%. When examined morphologically, it is seen that it is nanosized and synthesized approximately in the form of nanorods. It has been proven by STEM elemental mapping, Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1%MoS<sub>2</sub> contains Cd, Zn, S, and Mo. With DRS analysis, it is seen that the band gap decreases as MoS<sub>2</sub> is added. The direct band value for the highest hydrogen producing catalyst was calculated to be approximately 2.32 eV.

For the second part of the study, the aim was to synthesize a photocatalyst in nanorod form and utilizing the results obtained from optimization in the first part. The Cd<sub>0.7</sub>Zn<sub>0.3</sub>S catalyst was selected for synthesis in nanorod form. At this stage, one of the factors influencing the synthesis parameters, namely the solvent type, was altered, and EDA was

chosen. It was synthesized using 3 different EDA/water ratios. in Figure 4.11. as shown, the photocatalyst synthesized using 40 mL EDA and 40 mL water is in nanorod form. N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S photocatalyst showed 37.2 mmol g<sup>-1</sup> h<sup>-1</sup> hydrogen production. After, different percentages (1, 3, 5, 7, 10, and 15 %) of MoS<sub>2</sub> were added to increase the activity. N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub> photocatalyst, which had the highest hydrogen production, showed 131.8 mmol g<sup>-1</sup> h<sup>-1</sup> hydrogen production. This value increased by 3.5 times compared to its bare value. The same catalyst also gave the highest photocurrent difference in electrochemical measurements.

Then, MoC-Mo<sub>2</sub>C was synthesized by using CVD and added to Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub> photocatalyst in various percentages. N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1%MoS<sub>2</sub>/1.0%MoC-Mo<sub>2</sub>C photocatalyst showed the best results with 133.5 mmol H<sub>2</sub> g<sup>-1</sup> h<sup>-1</sup>. It has been found that hydrogen production is increased by adding the MoS<sub>2</sub>/MoC-Mo<sub>2</sub>C structure. In DRS analysis, the band gap of the N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub> photocatalyst was calculated to be approximately 2.36 eV, while the N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.0% MoC-Mo<sub>2</sub>C was calculated to be approximately 2.32 eV. Hydrogen production results and electrochemical measurements support each other. In this study, N-Cd<sub>0.7</sub>Zn<sub>0.3</sub>S/1% MoS<sub>2</sub>/1.0% MoC-Mo<sub>2</sub>C structure, which was proposed for the first time in the literature, was developed as a efficient and stable photocatalyst for H<sub>2</sub> production. It is aimed that the study will provide impact for the literature and hydrogen production applications.
