Date of Defense : 14 July 2020

To my family,

FOREWORD

Firstly, I would like to express my sincere thanks to my advisor Prof. Dr. Ercan Yüksel for his endless support, guidance and inspiration. It was an honor for me to work with him and benefit from his valuable knowledge and experience.

I would like to thank Asst. Prof. Dr. Ahmet Güllü as well for his guidance during the thesis.

I also give thanks to The Scientific and Technological Research Council of Turkey (TUBITAK) “2211 – National Graduate Scholarship Programme” for their financial support during my M.Sc. degree education.

July 2020

Furkan ÇALIM
(Civil Engineer)

ESTIMATIONS OF SEISMIC INPUT ENERGY AND INELASTIC TOP DISPLACEMENT DEMAND IN MOMENT RESISTING FRAME TYPE STRUCTURES

SUMMARY

Energy-based seismic design (*EBS*) methodology has an edge over force-based seismic design (*FBS*) and displacement-based seismic design (*DBS*) methodologies in many ways. Unlike *FBS* and *DBS* used in the current seismic design codes, it accounts for the type (near-fault, far-fault, etc.), frequency content, and total duration of the *EQ* record. Also, it takes the cumulative damage potential of an earthquake excitation into account.

A basis for the *EBS* was created in the content of this thesis study by proposing a methodology to calculate the seismic demands of a moment resisting frame fast and with an acceptable level of accuracy. Firstly, mass-normalized input energy response spectrum is calculated for *SDOF* systems using the ground acceleration and velocity response of the structure. Input energies (E_I) imparted into each story of a *MDOF* system are estimated using the suggested formula which uses mode shapes, modal participation factors, and E_I/m spectra constructed for *SDOF* systems. After total E_I per unit mass is estimated, maximum inelastic top displacement (δ_{top}) of a *MDOF* system during a seismic excitation is predicted using the proposed relation between E_I/m and δ_{top} .

Model frames and *EQ* records to be used in the application and verification of the methodology were selected and nonlinear time history analyses (*NLTHA*) were performed on the model frames using Perform 3D software. In order to make sure that the methodology can be applied on moment resisting frames using different materials and with different number of stories, three-story reinforced concrete *Manoukas* frame, three- and six-story steel *Akbas* frames, nine- and twenty-story steel *SAC-LA* frames were selected. For the selection of *EQ* records, energy-displacement capacity curves were calculated for the model frames using the force-displacement capacity curves that were obtained after running static push-over analyses. 92 *EQ* records causing a higher energy input to the frames than the yield energy were selected.

After seismic demands (input energy demands on story level and inelastic top displacement demand) of the set of 92 *EQ* records were estimated by the proposed methodology, they were compared with the results of the *NLTHA*. Relative percentage differences between the predicted and true values were computed.

Using all 92 *EQ* records, arithmetic means of the relative percentage differences in the prediction of total E_I/m , story E_I , and δ_{top} were computed as 12.6%, 19.5%, 19.6%, respectively for the steel frames and 38.6%, 37.0%, 53.1%, respectively for the *RC* frame.

Using the 35 *EQ* records with a *PGV* less than 50 m/s (ordinary non-pulse-like motion), arithmetic means of the relative percentage differences in the prediction of total E_I/m , story E_I , and δ_{top} were computed as 7.3%, 13.6%, 17.3%, respectively for the steel frames and 17.1%, 18.7%, 20.9%, respectively for the *RC* frame.

It was observed that the methodology yields better results for ordinary type *EQ* records ($PGV \leq 50$ m/s) compared to pulse-like type *EQ* records. For steel frames, it predicts the seismic demands with a very strong correlation. For *RC* frame, it predicts the seismic demands with a moderate correlation in the case of pulse-like records, and with a very strong correlation in the case of ordinary non-pulse-like records.

MOMENT AKTARAN ÇERÇEVE TÜRÜ YAPILARDA SİSMİK GİRİŞ ENERJİSİNİN VE İNELASTİK TEPE YERDEĞİŞTİRMESİ TALEBİNİN TAHMİN EDİLMESİ

ÖZET

Mevcut deprem yönetmeliklerinde (ASCE/SEI 7, FEMA 356, Eurocode 8, TBDY 2018 gibi) kuvvet esaslı ve yerdeğiştirme esaslı sismik tasarım yöntemleri kullanılmaktadır. Kuvvet esaslı tasarım yönteminde, daha önceden belirlenmiş bina performans hedefi için sistem sünekliği ve malzeme dayanım fazlalığı katsayısına karşı gelen azaltma katsayısı “ R ” belirlenir. Elastik ivme spektrumu kullanılarak elde edilen elastik deprem kuvvetleri R katsayısı ile küçültülerek tasarım deprem kuvvetleri hesaplanır. Bu azaltma, yapının tasarım deprem kuvvetleri altında doğrusal olmayan davranış göstereceği varsayılarak yapılır. Yapısal elemanların tasarım deprem kuvvetlerini güvenle taşıdığı durumda yeterli sismik tasarım elde edilmiş olur. Yerdeğiştirme esaslı tasarım yönteminde ise, öncelikle yapının kuvvet-yerdeğiştirme ilişkisi hesaplanır. Elde edilen kapasite eğrisi kullanılarak yapının yerdeğiştirme talepleri belirlenir. Yerdeğiştirme taleplerinin yönetmeliklerde verilen limitlerden daha az olduğu durumda yeterli sismik tasarım elde edilmiş olur.

Geleneksel sismik tasarım yöntemleri (kuvvet esaslı ve yerdeğiştirme esaslı) depreme ait bazı önemli özellikleri hesaba katmadıkları için güvenilir bir sismik tasarım ortaya koyma konusunda büyük bir eksikliğe sahiplerdir. Özellikle Türkiye gibi depreme sıklıkla maruz kalan ülkelerin yönetmeliklerinde bahsi geçen yöntemlerin kullanılması yerine, bu eksiklikleri bünyesinde barındırmayan yeni bir sismik tasarım yöntemi geliştirilmelidir.

Henüz mevcut yönetmeliklerde yer almayan enerji esaslı tasarım yöntemi ise bu yöntemlerin olumlu özelliklerini barındırmasına ek olarak; depremin türü, süresi ve frekans içeriği gibi kuvvet ve yerdeğiştirme esaslı yöntemlerce göz ardı edilen önemli özellikleri de dikkate almaktadır. Böylece enerji esaslı tasarım yöntemi, deprem süresine bağlı kümülatif hasar durumunu da göz ardı etmemesiyle, kuvvet ve yerdeğiştirme esaslı yöntemlere kıyasla daha güvenilir hale gelmektedir. Enerji esaslı sismik tasarım yönteminde, deprem hareketinden kaynaklanan enerji taleplerinin yapısal eleman enerji kapasitelerinden daha az olduğu durumda yeterli sismik tasarım elde edilmiş olur.

Tezin birinci bölümünde tezin amacından, literatürde konu ile ilgili daha önce yapılmış çalışmalardan ve tez ile birlikte sunulan hipotezden bahsedilmiştir.

Bu yüksek lisans tez çalışması ile; enerji esaslı sismik tasarım yöntemi geliştirilmesi kapsamında kullanılmak üzere, yapıların maruz kaldığı deprem hareketleri altında yapısal elemanlarda oluşacak inelastik tepe yerdeğiştirme taleplerinin ve sismik giriş enerjisinin katlar arasında dağıtılmasıyla enerji taleplerinin belirlenmesi için -doğrusal olmayan zaman tanım alanında analiz uygulayarak doğrulaması yapılmış- bir metodoloji geliştirilmesi hedeflenmektedir. Tez kapsamında geliştirilen metodoloji ile yapının sismik enerji ve yerdeğiştirme taleplerinin sadece deprem kaydı ve yapının

modal özellikleri kullanılarak hızlı ve doğru değerlere olabildiğince yakın bir şekilde tahmin edilmesi amaçlanmaktadır.

Tezin ikinci bölümünde Perform 3D yazılımında oluşturulan sayısal modellerden ve doğrusal olmayan zaman tanım alanında analizlerde kullanılan deprem kayıtlarından bahsedilmiştir. Tezde önerilen metodolojinin kontrolü ve doğrulamasını yapmak amacıyla farklı kat sayılarına sahip moment aktaran iki boyutlu çerçeve sistemler seçilmiştir. Tez içerisinde *Manoukas 3-St*, *Akbas 3-St*, *Akbas 6-St*, *SAC-LA 9-St* ve *SAC-LA 20-St* olarak adlandırılan, daha önce literatürdeki bazı çalışmalarda da kullanılmış olan üç katlı bir adet betonarme ve üç, altı, dokuz, yirmi katlı dört adet çelik olmak üzere toplam beş adet moment aktaran çerçeve sistem seçilmiştir. Yapısal elemanların doğrusal olmayan davranışını hesaba katmak için plastik mafsallı teorisi kullanılmış ve elemanların her iki ucuna plastik mafsallar tanımlanırken orta kısımları ise elastik tanımlanmıştır. Plastik mafsallı uzunlukları, her bir kesit yüksekliğinin yarısı olarak alınmıştır.

Deprem kayıtlarının seçimi için öncelikle model çerçevelere statik itme analizi yapılarak kuvvet-yerdeğiştirme kapasite eğrisi elde edilmiştir. Sonrasında ise enerji-yerdeğiştirme kapasite eğrisi hesaplanmış ve her bir model yapıya ait akma enerjisi değerleri elde edilmiştir. *Akbas 3-St*, *Akbas 6-St*, *SAC-LA 9-St*, *SAC-LA 20-St* çelik çerçeveleri için akma enerjileri sırasıyla $0.156 \text{ m}^2/\text{s}^2$, $0.208 \text{ m}^2/\text{s}^2$, $0.402 \text{ m}^2/\text{s}^2$ ve $0.307 \text{ m}^2/\text{s}^2$ olarak hesaplanmıştır. Akma enerjisinden daha yüksek bir enerji girişine sebep olacak 92 adet deprem kaydı, toplam 1094 deprem kaydı arasından seçilmiştir. Analizler sırasında %5 sönüm oranı kullanılmıştır. Ayrıca kayıtlarda herhangi bir ölçeklendirme yapılmamış, dolayısıyla seçilen deprem kayıtlarının içeriği bozulmamıştır.

Seçilen 92 deprem kaydından 32 tanesi uzak deprem karakteristiklerini içerisinde barındıran “ordinary non-pulse-like”, 60 tanesi ise yakın fay depremi karakteristiklerini içerisinde barındıran “pulse-like” kayıtlardır. Yakın fay depremleri genellikle yapılarda daha yüksek sismik taleplerin (taban kesme kuvveti, kat yerdeğiştirmeleri, sismik giriş enerjisi, v.s.) oluşmasına sebep olurlar ve genellikle yüksek *PGV* (en büyük yer hızı) değerine sahiplerdir. Tez kapsamında önerilen metodolojinin uzak deprem kayıtları için, veya başka bir deyişle *PGV* değeri daha az olan deprem kayıtları için ($PGV \leq 50 \text{ cm/s}$) çok daha iyi sonuç verdiği görülmüştür.

Tezin üçüncü bölümünde bir deprem hareketi sırasında çok serbestlik dereceli sistemlere (*ÇSDS*) etkiyen maksimum giriş enerjisinin tahmini için önerilen yöntemden bahsedilmiştir. Önerilen yöntemde, kümülatif olarak bina toplam kütesinin %95’inden daha fazla modal etkin kütleli sağlayacak sayıda mod kullanılmıştır. Bu bağlamda *Manoukas 3-St* ve *Akbas 3-St* çerçeveleri için ikişer mod (sırasıyla %96.58 ve %97.01 kümülatif modal etkin kütle), *Akbas 6-St*, *SAC-LA 9-St*, *SAC-LA 20-St* çerçeveleri için ise üçer mod (sırasıyla %97.10, %97.70 ve %95.16 kümülatif modal etkin kütle) kullanılmıştır.

Öncelikle her bir deprem kaydı kullanılarak tek serbestlik dereceli sistemlere (*TSDS*) ait giriş enerjisi spektrumu oluşturulmuştur. Yapıya ait mod şekli, modal katkı çarpanı ve *TSDS* için oluşturulmuş giriş enerjisi spektrumu kullanılarak bir formülasyon önerilmiş ve *ÇSDS* için maksimum giriş enerjisi tahmin edilmeye çalışılmıştır. Tahmin edilen giriş enerjisi değerleri sonraki bölümlerde önce inelastik tepe yerdeğiştirmesi, sonrasında ise kat yerdeğiştirmelerinin tahmininde kullanılacağı için yapılan tahminlerin gerçek değerlere oldukça yakın olması gerekmektedir.

Giriş enerjisi tahmini için 92 adet deprem kaydı kullanılarak elde edilen sonuçlar, doğrusal olmayan zaman tanım alanında analiz sonuçları ile karşılaştırılmış ve *Manoukas 3-St, Akbas 3-St, Akbas 6-St, SAC-LA 9-St, SAC-LA 20-St* çerçeveleri için rölatif yüzde farklarının aritmetik ortalamaları sırasıyla %38.6, %11.3, %13.6, %11.7 ve %13.9 olarak hesaplanmıştır. Korelasyon katsayıları ise sırasıyla 0.739, 0.974, 0.932, 0.959 ve 0.914 olarak hesaplanmıştır. Bu sonuçlar, çelik çerçeveler için tahminlerin çok yüksek korelasyon derecesi ile, betonarme çerçeve için ise tahminlerin yüksek korelasyon derecesi ile yapıldığını göstermektedir.

Giriş enerjisi tahmini için 50 cm/s daha düşük bir *PGV* değerine sahip 35 adet deprem kaydı kullanıldığında *Manoukas 3-St, Akbas 3-St, Akbas 6-St, SAC-LA 9-St, SAC-LA 20-St* çerçeveleri için rölatif yüzde farklarının aritmetik ortalamaları sırasıyla %17.1, %5.8, %7.7, %6.0 ve %9.3 olarak hesaplanmıştır.

Tezin dördüncü bölümünde moment aktaran çerçeveye etkiyen toplam giriş enerjisinin yapının katları arasında dağıtılmasından bahsedilmiştir. Literatürde giriş enerjisinin katlar arasında dağılımının tahminine yönelik bir çalışma olmazken, histeretik enerjinin dağılımına yoğunlaşmıştır. Literatürdeki bir çok çalışmada deprem karakteristiklerinden bağımsız olarak yapının sadece modal özellikleri kullanılarak histeretik enerji dağılımının tahmin edilmesine çalışılmış, dolayısıyla her yapı için tek bir enerji dağılım düzeni önerilmiştir. Ancak bu tezde elde edilen doğrusal olmayan zaman tanım alanında analiz sonuçları da göstermiştir ki, enerji dağılımını deprem kaydından bağımsız olarak temsil etmek mümkün değildir. Bu yüzden, bir önceki bölümde önerilen ve her bir deprem kaydına özgü giriş enerjisi spektrumunun kullanıldığı yöntem ile giriş enerjisinin katlar arasında dağılımı düşük rölatif yüzde farkları ile tahmin edilebilmektedir.

Giriş enerjisinin yapıların katları arasında dağıtılmasının tahmini için 92 adet deprem kaydı kullanılarak elde edilen sonuçlar, doğrusal olmayan zaman tanım alanında analiz sonuçları ile karşılaştırılmış ve *Manoukas 3-St, Akbas 3-St, Akbas 6-St, SAC-LA 9-St, SAC-LA 20-St* çerçeveleri için rölatif yüzde farklarının aritmetik ortalamaları sırasıyla %37.0, %15.4, %16.9, %16.5 ve %29.4 olarak hesaplanmıştır.

Giriş enerjisi yapıların katları arasında dağıtılmasının tahmini için 50 cm/s daha düşük bir *PGV* değerine sahip 35 adet deprem kaydı kullanıldığında *Manoukas 3-St, Akbas 3-St, Akbas 6-St, SAC-LA 9-St, SAC-LA 20-St* çerçeveleri için rölatif yüzde farklarının aritmetik ortalamaları sırasıyla %18.7, %13.1, %12.3, %10.1 ve %19.3 olarak hesaplanmıştır.

Tezin beşinci bölümünde ise yapının inelastik tepe yerdeğiştirmesi talebinin tahmini için önerilen yöntemden bahsedilmiştir. Literatürde bulunan ve giriş enerjisi ile tepe yerdeğiştirme arasındaki ilişkiyi gösteren formülasyon, yapının diğer modlarının katkısını da göz önünde bulundurmak için tanımlanan “referans periyot, T_{ref} ” kullanılarak güncellenmiş ve tezin üçüncü bölümünde tahmin edilen giriş enerjisi kullanılarak yapının maksimum tepe yerdeğiştirmesi tahmin edilmiştir. Bu yöntemle göre, giriş enerjisi ile maksimum tepe deplasmanı arasında ikinci dereceden parabolik bir ilişki elde edilmiştir.

Yapının bir deprem hareketi sırasında meydana gelen maksimum tepe yerdeğiştirmesi değeri genel doğrusal olmayan statik prosedürler için bir giriş bilgisi olarak kullanıldığından, bu değer inelastik olduğundan az bir rölatif hata ile tahmin edilebilmesi önem arz etmektedir.

Tepe yerdeđiřtirmesi tahmini iin 92 adet deprem kaydı kullanılarak elde edilen sonular, dođrusal olmayan zaman tanım alanında analiz sonuları ile karřılařtırılmıř ve *Manoukas 3-St*, *Akbas 3-St*, *Akbas 6-St*, *SAC-LA 9-St*, *SAC-LA 20-St* ereveleri iin rlatif yzde farklarının aritmetik ortalamaları sırasıyla %53.1, %18.3, %20.6, %18.8 ve %20.9 olarak hesaplanmıřtır. Korelasyon katsayıları ise sırasıyla 0.546, 0.857, 0.849, 0.878 ve 0.883 olarak hesaplanmıřtır. Bu sonular, elik ereveler iin tahminlerin ok yksek korelasyon derecesi ile, betonarme ereve iin ise tahminlerin orta korelasyon derecesi ile yapıldıđını gstermektedir.

Tepe yerdeđiřtirmesi tahmini iin 50 cm/s'den daha dřk bir *PGV* deđerine sahip 35 adet deprem kaydı kullanıldıđında *Manoukas 3-St*, *Akbas 3-St*, *Akbas 6-St*, *SAC-LA 9-St*, *SAC-LA 20-St* ereveleri iin rlatif yzde farklarının aritmetik ortalamaları sırasıyla %20.9, %15.8, %14.8, %19.8 ve %18.8 olarak hesaplanmıřtır.

Tez kapsamında nerilen metodoloji ile, sismik giriř enerjisi ve inelastik tepe yerdeđiřtirmesi tahminlerini elik ereveler iin ok yksek korelasyon derecesi ile yapmak mmknken, betonarme ereve iin tahminler sadece uzak deprem ($PGV \leq 50$ cm/s) durumunda ok yksek korelasyon derecesi ile yapılabilmektedir.

1. INTRODUCTION

In the current seismic design codes (such as ASCE/SEI 7, FEMA 356, Eurocode 8, and TBEC 2018: Turkish Building Earthquake Code-2018), two design philosophies are used, namely force-based seismic design (*FBSD*) and displacement-based seismic design (*DBSD*). In *FBSD*, a reduction factor “*R*” corresponding to the ductility of the structure is determined for predefined target performance level. Elastic forces obtained using the elastic acceleration spectrum are reduced by the factor *R* to calculate the design seismic forces. This reduction is implemented by assuming the structure will show inelastic nonlinear behavior under the design seismic forces. The satisfactory design is obtained when the structural members can safely carry the design seismic forces. In *DBSD*, force-displacement relation of the structure is obtained with the nonlinear modelling strategy. Displacement demand of the structure is then calculated using the structural capacity curve. The satisfactory design is obtained when the displacement demand is less than or equal to the limits given in the design codes corresponding to the preventive performance level.

However, these approaches disregard some important earthquake-dependent parameters such as the frequency content and duration of the excitation. They only consider the peak responses in the assessment of demands of the structures. Because of the deficiencies in *FBSD* and *DBSD*, a more extensive design philosophy was needed. Thus, “Energy Based Seismic Design” (*EBSD*) is firstly introduced by Housner in 1956 and studied by many researchers since. *EBSD* can be considered as a more reliable design procedure as it also accounts for the cumulative damage potential of the earthquake record alongside comprising the positive sides of the current design methodologies.

Two unscaled earthquake records with similar *PGA* values but different total durations (Chile Llole, 1985 and San Salvador, 1986) were selected in order to demonstrate the deficiencies in the current seismic design methodologies, Figure 1.1. They result in almost the same acceleration spectra (Figure 1.2) but quite different input energy spectra (Figure 1.3) for 5% damping ratio. Since some parameters like earthquake

duration are not considered in the traditional design methods, similar seismic demands are obtained using the acceleration spectra. Yet, more realistic seismic demands are obtained using the input energy spectra in *EBS*.

Figure 1.1 : Ground accelerations: (a) Chile Lolloe. (b) San Salvador.

Figure 1.2 : Acceleration spectra for the sample *EQ* records.

Figure 1.3 : Input energy spectra for the sample *EQ* records.

1.1 Purpose of Thesis

With this M.Sc. thesis, it is aimed to propose a methodology in order to determine the earthquake demands of moment resisting frame type structures using energy-based approach. Using the proposed methodology; the seismic input energy imparted into a structure during an earthquake, its distribution among the stories, and inelastic top displacement demand are expected to be estimated with a high precision only using the modal properties of the structure and the input energy spectrum of the earthquake record.

1.2 Literature Review

External and internal energy terms can be obtained using the dynamic equation of motion of a *SDOF* system under a seismic excitation, equation (1.1) where “*m*” is mass, “*c*” is damping, “*k*” is stiffness, “*u*” is displacement response, “*u̇*” is velocity response, “*ü*” is acceleration response of the system, and “*ü_g*” is ground acceleration.

$$m \cdot \ddot{u}(t) + c \cdot \dot{u}(t) + k \cdot u(t) = -m \cdot \ddot{u}_g(t) \quad (1.1)$$

Multiplying both sides of the equation (1.1) by “*u̇dt*” term and integrating it over the total earthquake duration yields equation (1.2). Left-hand side of the equation represents the energy components of the structure, namely kinetic energy (*E_k*), damping energy (*E_d*) which is the amount of dissipated energy due to damping, and

strain energy (E_s) which is composed of recoverable elastic and irrecoverable inelastic energies. Right-hand side of the equation represents the input energy (E_I), equation (1.3) (Akiyama, 1985).

$$m \int_0^t \ddot{u}(t) \cdot \dot{u}(t) dt + c \int_0^t \dot{u}(t) \cdot \dot{u}(t) dt + k \int_0^t u(t) \cdot \dot{u}(t) dt = -m \int_0^t \ddot{u}_g(t) \cdot \dot{u}(t) dt \quad (1.2)$$

$$E_k + E_d + E_s = E_I \quad (1.3)$$

In order to calculate the mass-normalized input energy for a *SDOF* system, Akiyama (1985) proposed empirical relation, equation (1.4). The equivalent velocity (V_E) used in the estimation of the input energy per unit mass is calculated using the predominant period of the ground motion (T_c), equation (1.5).

$$E_I / m = \frac{V_E^2}{2} \quad (1.4)$$

$$V_E = \begin{cases} 2.5T & T \leq T_c \\ 2.5T_c & T > T_c \end{cases} \quad (1.5)$$

Kuwamura and Galambos (1989) used the same equation with Akiyama but recommended equation (1.6) in the calculation of V_E . “ I_e ” term is calculated using equation (1.7).

$$V_E = \begin{cases} \frac{\sqrt{T_c I_e} 1.2T}{2 T_c} & T \leq T_c \\ \frac{\sqrt{T_c I_e}}{2} & T > T_c \end{cases} \quad (1.6)$$

$$I_e = \int_0^t \ddot{u}_g^2(t) dt \quad (1.7)$$

Two methods are suggested by Uang and Bertero (1990) to calculate mass-normalized input energy. In the first method, it was calculated by derivation of the absolute equation of motion, equation (1.8) whereas in the second method, it was calculated by derivation of the relative equation of motion, equation (1.9). Idea of calculating the

input energy in terms of the relative equation of motion as in equation (1.9) is considered to be more reasonable in the literature.

$$E_I / m = \int_0^t \dot{u}_g(t) \cdot \ddot{u}(t) dt \quad (1.8)$$

$$E_I / m = - \int_0^t \ddot{u}_g(t) \cdot \dot{u}(t) dt \quad (1.9)$$

In order to obtain a reliable relationship between the energy and displacement demands, Fajfar (1992) and Fajfar and Vidic (1994) proposed a non-dimensional parameter (γ) for *SDOF* systems, equation (1.10). With this expression, mass normalized dissipated hysteretic energy (E_H) and the maximum displacement of a *SDOF* system (δ) are correlated.

$$\gamma = \frac{\sqrt{E_H / m}}{\omega \times \delta} \quad (1.10)$$

Teran-Gilmore (1996) suggested a more stable parameter (ζ) to indicate the relation between energy and displacement demand of *SDOF* systems where input energy (E_I) is used instead of dissipated hysteretic energy (E_H), equation (1.11).

$$\zeta = \frac{\sqrt{E_I / m}}{\omega \times \delta} \quad (1.11)$$

For the application of these expressions on *MDOF* systems, Mollaioli et al. (2011) studied the correlation between top displacement demand of a *MDOF* system and energy demand in terms of both E_H and E_I . In this study, equations (1.10) and (1.11) were modified using the angular frequency corresponding to the first mode (ω_1) and top displacement of the structure (δ_{top}) and two new parameters (γ' and ζ') were introduced, equations (1.12) and (1.13).

$$\gamma' = \frac{\sqrt{E_H / m}}{\omega_1 \times \delta_{top}} \quad (1.12)$$

$$\zeta' = \frac{\sqrt{E_I / m}}{\omega_1 \times \delta_{top}} \quad (1.13)$$

By the suggestion of two new parameters, it is now possible to determine the maximum displacement of *SDOF* systems and the maximum top displacement of *MDOF* systems using both input energy and hysteretic energy approaches (Mollaioli et al, 2011). In this study, calculating the seismic demands of *MDOF* systems using the input energy will be the focus of interest, Figure 1.4.

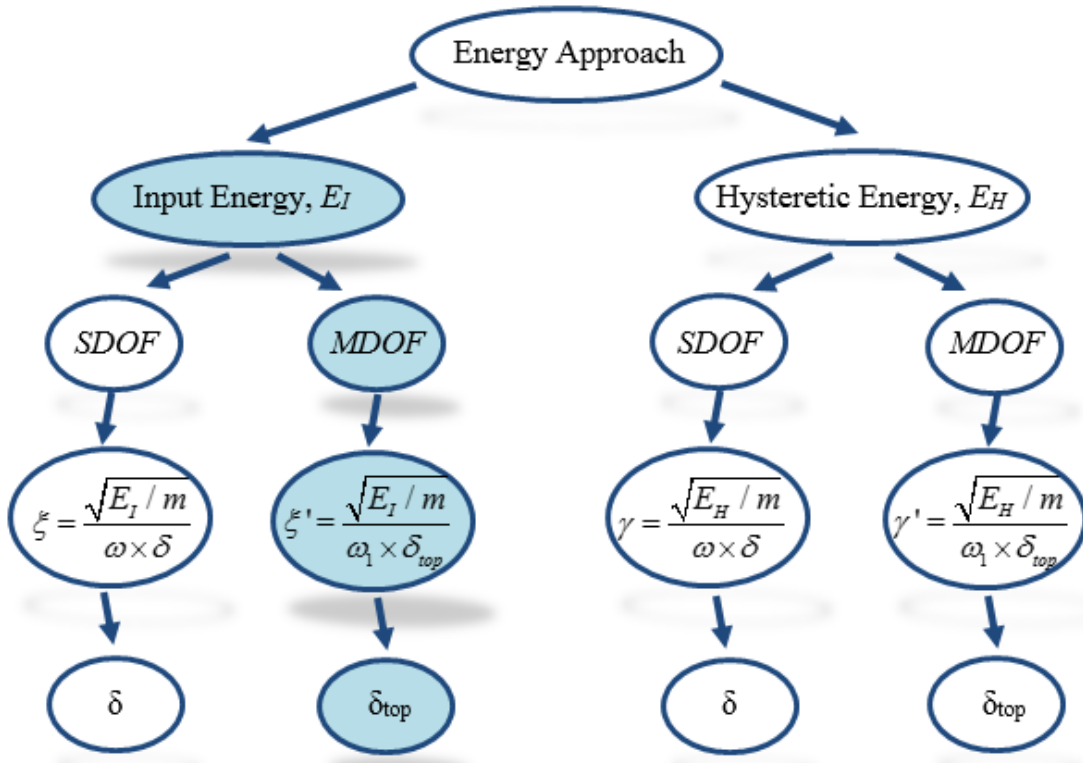

Figure 1.4 : Energy approaches for the determination of δ_{top} .

The change in the parameter ζ' , which was defined in order to associate the energy with the top displacement demand in *MDOF* systems using input energy approach, with respect to period for different types of stiffness patterns is shown in Figure 1.5. Here, the stiffness pattern A represents parabolic stiffness distribution along the height of a stiff foundation structure, the stiffness pattern B represents parabolic stiffness distribution along the height of a flexible foundation structure, and the stiffness pattern U represents uniform stiffness distribution along the height of a stiff foundation structure (Mollaioli et al, 2011). It can be observed that the parameter ζ' is almost pegged on the value of 0.80 after $T = 0.75$ s for all three stiffness patterns.

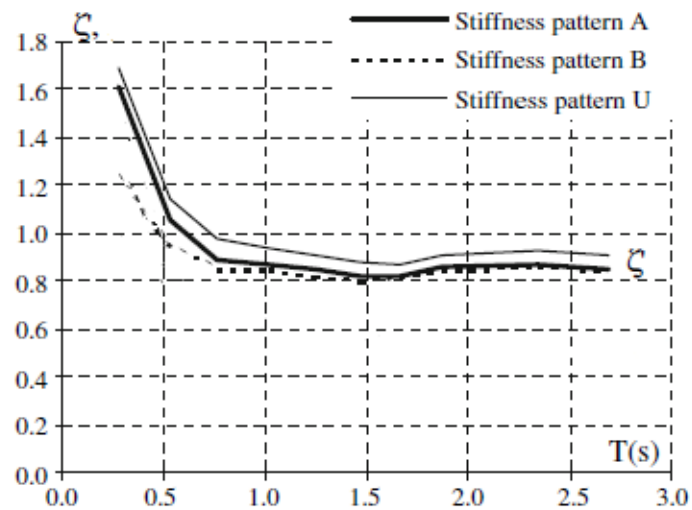

Figure 1.5 : ζ' spectra (Mollaioli et al, 2011).

1.3 Hypothesis

Seismic input energy of a *MDOF* system can be estimated on story levels by means of its modal properties and the energy spectrum obtained for a *SDOF* system. Using the predicted input energy, inelastic top displacement demand of a frame type system can be calculated. Thus, a basis for the energy-based seismic design (*EBSD*) is created with this M.Sc. thesis by proposing a methodology to determine the seismic demands (input energy and inelastic displacement) of moment resisting frame type structures.

2. NUMERICAL MODELS

In order to compute the seismic input energy for each *MDOF* model frame under the effect of different seismic excitations, Perform 3D software was used in the modelling of the frames and performing the nonlinear time history analysis. The program computes input energy with an acceptable numerical accuracy as it provides an energy balance between internal (strain, kinetic, inelastic, and damping) energies and external (input) energy.

2.1 Selected Model Frames

In this study, seismic input energy and inelastic displacement demand estimations were carried out for a set of five model frames which are three-story reinforced concrete frame and three-, six-, nine-, and twenty-story steel frames. The model frames to be used in the application and verification of the methodology have been studied on in the literature before.

2.1.1 Three-story reinforced concrete frame

The three-story and one-bay frame used by Manoukas et al. (2011) was selected as the only *RC* frame to be used in this study, Figure 2.1. The frame has a bay width of 4.0 m and a story height of 4.0 m. The columns are fixed at the base. The columns have a rectangular cross-section of 40×40 with 8Φ16 longitudinal reinforcement. The beams have a rectangular cross-section of 25×40 with 4Φ12 longitudinal reinforcement. Concrete quality of C16/20 is used whereas the reinforcing bars are S400. Seismic mass of the structure is 30 tons in total (each story is 10 tons).

Natural periods, effective masses, and modal participation factors of the three-story *RC* frame (*Manoukas 3-St*) are listed in Table 2.1. Normalized mode shapes to be used in the following chapters are shown in Table 2.2 for the first three modes.

Figure 2.1 : *Manoukas* 3-St frame.

2	0.177	-0.161	-0.203
3	0.249	0.175	0.078

2.1.2 Three-story steel frame

The three-story and four-bay frame used by Akbas et al. (2001) was selected as the low-rise steel frame to be used in this study, Figure 2.2. The frame has a bay width of 9.15 m and a story height of 4.27 m for the first story and 3.51 m for the rest. The columns are fixed at the base. W360×122 and W360×262 sections are used as column elements whereas W460×52 and W610×101 sections are used as beam elements. A36 steel is used in both columns and beams. Seismic mass of the structure is 515 kNs²/m in total.

Natural periods, effective masses, and modal participation factors of the three-story steel frame (*Akbas 3-St*) are listed in Table 2.3. Normalized mode shapes to be used in the following chapters are shown in Table 2.4 for the first three modes.

2.1.3 Six-story steel frame

The six-story and four-bay frame used by Akbas et al. (2001) was selected as one of the mid-rise steel frames to be used in this study, Figure 2.3. The frame has a bay width of 9.15 m and a story height of 4.27 m for the first story and 3.51 m for the rest. The columns are fixed at the base. W360×147, W360×179, and W360×314 sections are used as column elements whereas W610×82 and W610×101 sections are used as beam elements. A36 steel is used in both columns and beams. Seismic mass of the structure is 1076 kNs²/m in total.

Natural periods, effective masses, and modal participation factors of the six-story steel frame (*Akbas 6-St*) are listed in Table 2.5. Normalized mode shapes to be used in the following chapters are shown in Table 2.6 for the first three modes.

Figure 2.3 : *Akbas 6-St* frame.

2.1.4 Nine-story steel frame

The nine-story and five-bay frame used by Gupta and Krawinkler (1999) was selected as one of the mid-rise steel frames to be used in this study, Figure 2.4. The frame has a bay width of 9.15 m and a story height of 5.49 m for the first story and 3.96 m for the rest. It also has a basement story with a height of 3.65 m. The columns are pinned at the base. A36 steel is used in beams and A572 Gr. 50 steel is used in columns. Seismic mass of the structure is 4500 kNs²/m in total.

Natural periods, effective masses, and modal participation factors of the nine-story steel frame (SAC-LA 9-St) are listed in Table 2.7. Normalized mode shapes to be used in the following chapters are shown in Table 2.8 for the first three modes.

2.1.5 Twenty-story steel frame

The twenty-story and five-bay frame used by Gupta and Krawinkler (1999) was selected as the high-rise steel frame to be used in this study, Figure 2.5. The frame has a bay width of 6.10 m and a story height of 5.49 m for the first story and 3.96 m for the rest. It also has two basement stories with a height of 3.65 m. The columns are pinned at the base. A36 steel is used in beams and A572 Gr. 50 steel is used in columns. Seismic mass of the structure is 5526 kNs²/m in total.

Natural periods, effective masses, and modal participation factors of the twenty-story steel frame (SAC-LA 20-St) are listed in Table 2.9. Normalized mode shapes to be used in the following chapters are shown in Table 2.10 for the first three modes.

2.2 Modelling Strategy

After the set of five model frames were drawn in Perform 3D software, movement of the frame was restricted in H2 direction by assigning supports at every joint in order to perform the analysis in plane frame. Self and additional masses were concentrated on the joints, Figure 2.6.

For all the systems, a damping ratio of 5% was considered in the analyses.

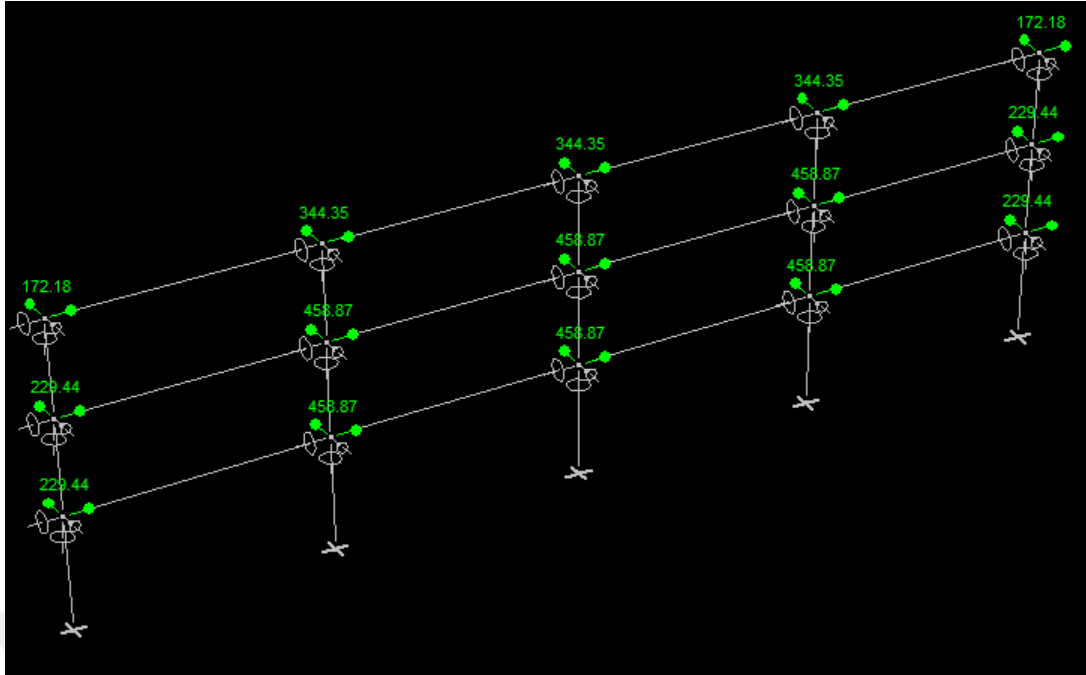

Figure 2.6 : Perform 3D model for Akbas 3-St frame.

Using the plastic hinge theory, nonlinear behavior of the frame elements was taken into account. While middle section of the members was considered to behave elastic under the excitation, the curvature type plastic hinges were assigned at the end sections. For the beam type frame elements, curvature type moment hinges were defined whereas for the column type frame elements, curvature type P-M2-M3 hinges were defined at the end zones of the frame elements. Material models of the middle section were represented by linear force-displacement relation, Figure 2.7 (a). Material models of the end sections were represented by elastic-perfectly plastic (e-p-p) force-displacement relation with no cyclic degradation, Figure 2.7 (b).

Figure 2.7 : Basic F-D relationship: (a) Middle section. (b) End sections.

For P-M2-M3 type plastic hinges assigned to the column elements, yield surface parameters were defined. P exponent (α) was taken as 2.0 for P-M2 and P-M3 interactions in both compression and tension regions. M exponent (β) was taken as

1.1 for P-M interaction. M exponent (gamma) was taken as 1.4 for M-M interaction, Figure 2.8.

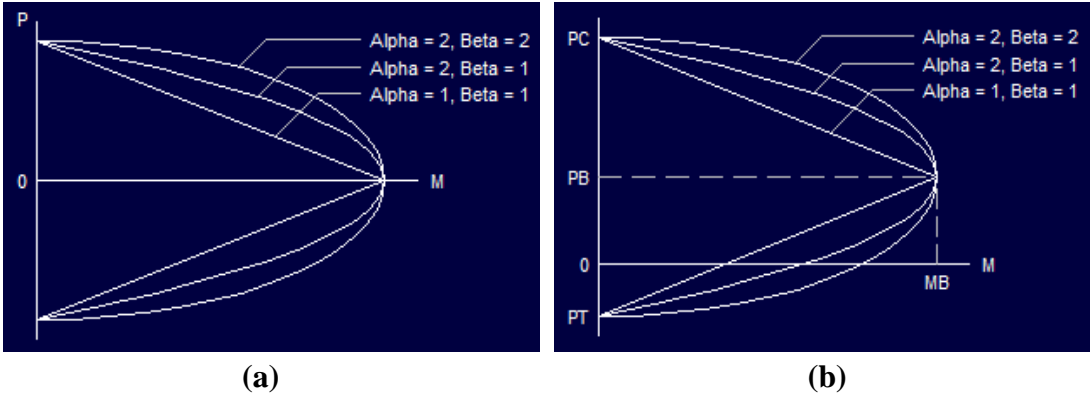

Figure 2.8 : P-M interaction yield surface parameters: (a) Steel sections. (b) RC sections.

In order to define the inelastic section properties of the plastic hinges, Xtrack software was used. First, bilinear material properties were defined. For the beam sections, moment-curvature relationship about x-axis was obtained and maximum moment value was defined as “axis 3 bending” in Perform 3D, Figure 2.9. For the column sections, P-M interaction diagram and moment-curvature relationship about both x- and y-axis were obtained. Axial force values for pure tension and pure compression cases were defined as “tension” and “compression”, maximum moment value about x-axis was defined as “axis 3 bending”, and maximum moment value about y-axis was defined as “axis 2 bending” in Perform 3D, Figure 2.10.

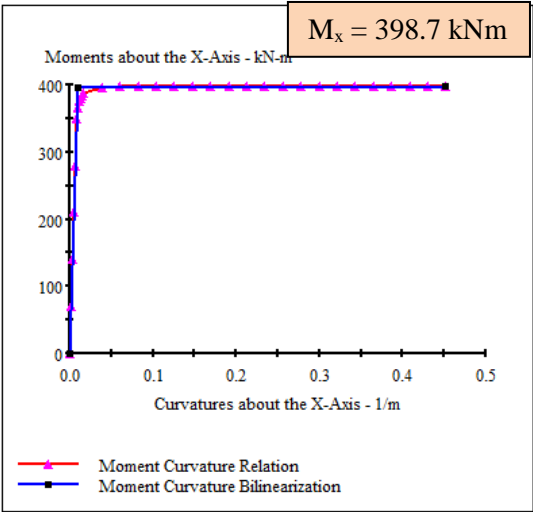

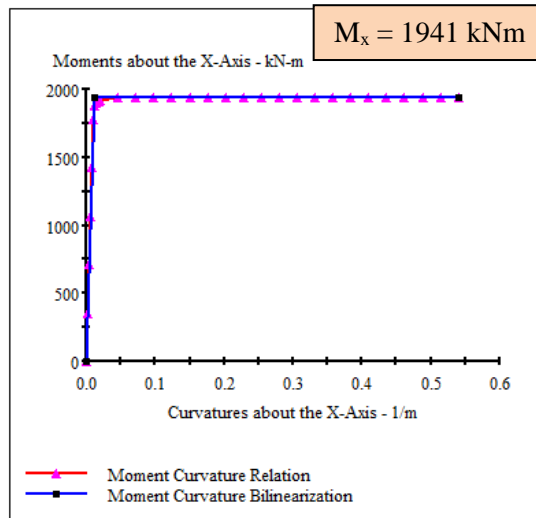

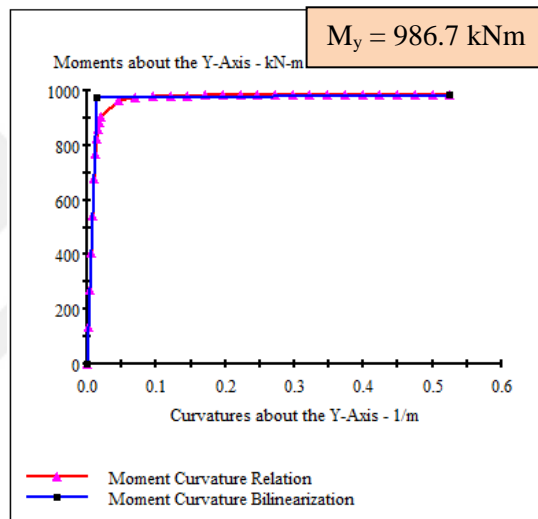

Figure 2.9 : Section properties for a sample beam section (W460x52).

(a) Moment-curvature relationship about x-axis (“axis 3 bending”)

(b) Moment-curvature relationship about y-axis (“axis 2 bending”)

(c) P-M interaction diagram (“tension” and “compression”)

Figure 2.10 : Section properties for a sample column section (W360×262).

After elastic region and plastic hinges were defined for all the structural members, compounds were generated. The length of the plastic hinges was taken as half of the section height, Figure 2.11 (a). For the column sections, P-M2-M3 hinges were defined at both ends, Figure 2.11 (b). For the beam sections, moment hinges were defined at both ends, Figure 2.11 (c).

No.	Component Type	Component Name	Length	Propn

2.3 Selection of the Earthquake Records

In order to determine the yield energy values for the set of four model frames, push-over analyses were performed using the first mode load patterns. After force-displacement capacity curves were obtained, energy-displacement capacity curve for each model frame was calculated and yield energies were obtained (Figure 2.12) where the force-displacement capacity curve is shown with orange and the energy-displacement capacity curve is shown with blue.

Using *PEER NGA* database, a total of 1094 earthquake records were downloaded. Among those, 92 earthquake records which cause a seismic input energy larger than the yield energy were selected. Earthquake records to be used in the nonlinear time history analysis are listed in Table A.1.

Figure 2.12 : Energy-displacement capacity curves and calculated yield energy values.

Both ordinary type and pulse-like type records were selected and split into groups in terms of V_{s30} , the average shear-wave velocity in the top 30 m of the soil, as shown in Table 2.11. In total, 32 ordinary type and 60 pulse-like type *EQ* records were used in the analyses and no scaling was made.

The pulse-like *EQ* ground motions generally have the characteristics of low frequency and cause higher seismic responses (base shear, story displacements, input energy, etc.) compared to the ordinary non-pulse-like *EQ* ground motions. Near-fault ground motions can often be classified as pulse-like type records whereas far-fault ground motions can often be classified as ordinary type records. Peak ground velocity (*PGV*) can be used as an indicator of the *EQ* type (pulse-like / ordinary non-pulse-like). *PGV* values for the set of 92 *EQ* records are listed in Table 2.12. Here, it can be seen that the ordinary non-pulse-like records (the ones shown with red color) generally have lower *PGV* values compared to the pulse-like records.

Table 2.11 : Classification of the chosen earthquake records.

Group #	Description	EQ #
G1	Ordinary Records with $V_{s30} < 180$	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13
G2	Pulse-Like Records with $V_{s30} < 180$	14, 15, 16, 17, 18, 19, 20, 21, 22
G3	Ordinary Records with $180 \leq V_{s30} < 360$	23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37

3. SEISMIC INPUT ENERGY ESTIMATION

Seismic input energy should first be accurately calculated in order to make an estimation about the inelastic top displacement demand of a structure. After seismic input energy spectrum for a *SDOF* system is obtained, total input energy amount that a *MDOF* system is subjected to during a seismic excitation can be estimated with the suggested method.

3.1 Seismic Input Energy Spectrum

A MATLAB based code was generated in order to obtain seismic input energy spectrum for *SDOF* systems. As the first step, earthquake responses (u , \dot{u} , and \ddot{u}) were calculated as a function of time using the “Piecewise Exact Method” for a series of oscillators constructed with the same mass but different rigidities, thus different natural vibration periods (Figure 3.1). Then, calculated velocity response (\dot{u}) was multiplied with the ground acceleration and integrated over the total duration of the excitation, equation (1.9). Finally, seismic input energy spectrum for a *SDOF* system was constructed plotting absolute maximum values of the time series for each oscillator with respect to natural vibration periods (Figure 3.2). The mass-normalized input energy spectra for all 92 *EQ* records are shown in Figure A.1.

Figure 3.1 : Oscillators with different natural vibration periods.

Figure 3.2 : Obtaining input energy spectrum for a sample *EQ* record.

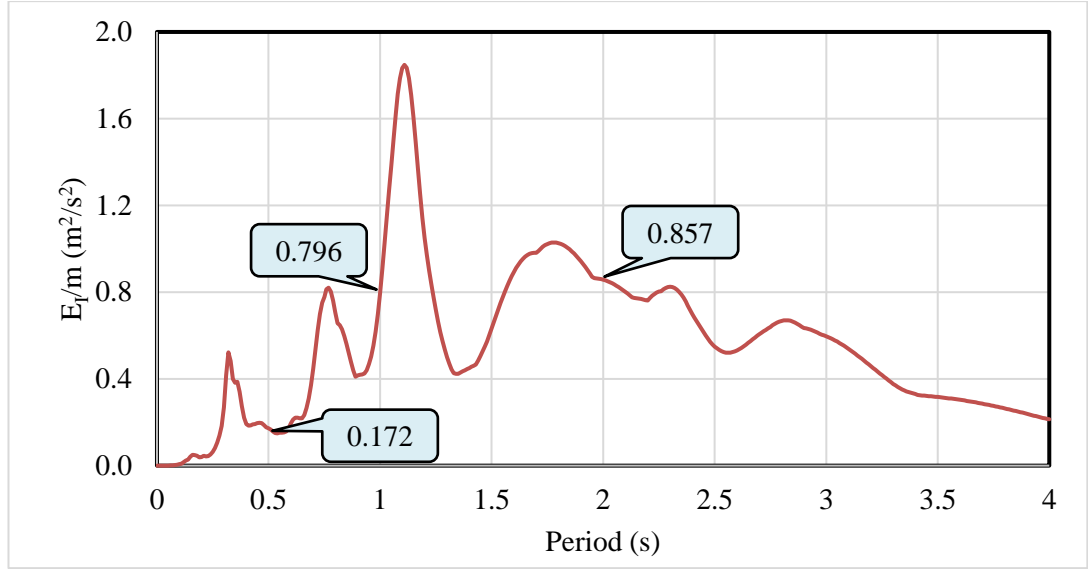

Figure 3.2 (continued) : Obtaining input energy spectrum for a sample *EQ* record.

3.2 Suggested Method to Estimate the Seismic Input Energy for *MDOF* Systems

The method requires the usage of dynamic properties of the structures, as shown in Table 2.1 and 2.2 for the selected set of model frames. The number of modes to be used in the analysis is taken as the mode number making the cumulative summation of the effective masses greater than 95% of the total mass. For three-story *Manoukas* frame and three-story *Akbas* frame, two modes with a cumulative summation of the effective masses of 96.58% and 97.01%, respectively were used in the analysis. For six-story *Akbas* frame, nine- and twenty-story *SAC-LA* frames, three modes with a cumulative summation of the effective masses of 97.10%, 97.70%, and 95.16%, respectively were considered in the application of the methodology.

Using the proposed method, seismic input energy per unit mass for a *MDOF* system can be estimated by equation (3.1), where N is the number of modes used in the analysis, n is the number of degrees of freedom, Φ_{ij} is the i^{th} story mode shape for the j^{th} mode, Γ_j is the modal participation factor, and $(E_I/m)_j$ is the mass-normalized input energies corresponding to each period in the input energy spectrum, Figure 3.3.

$$(E_I / m) = \frac{\sum_{j=1}^N \sum_{i=1}^n \phi_{ij} \cdot (E_I/m)_j \cdot \Gamma_j}{\sum_{j=1}^N \sum_{i=1}^n \phi_{ij} \cdot \Gamma_j} \quad (3.1)$$

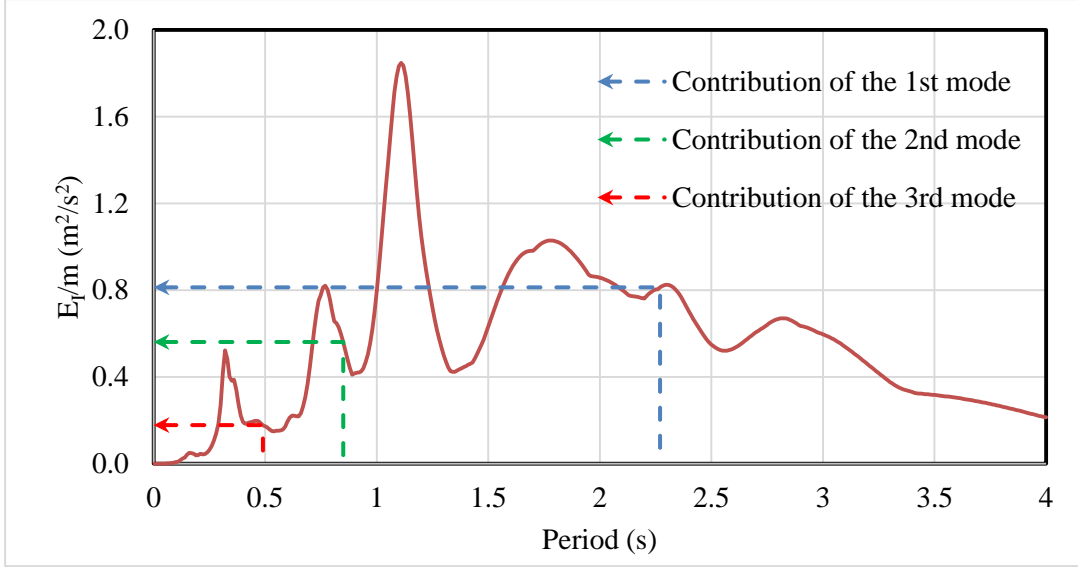

Figure 3.3 : Mass-normalized input energies corresponding to each mode.

Mass-normalized input energy predictions $((E_I / m)_{pre})$ were made using the suggested method in this study, equation (3.1). After that, they were compared with the numerical results obtained after running nonlinear time history analysis for a total of 92 earthquake records in five model structures in Perform 3D software $((E_I / m)_{num})$. The relative percentage differences between the predictions and numerical results (ε_{EI}) were calculated using equation (3.2).

$$\varepsilon_{EI} = \frac{|(E_I / m)_{pre} - (E_I / m)_{num}|}{\left[\frac{(E_I / m)_{pre} + (E_I / m)_{num}}{2} \right]} \quad (3.2)$$

3.3 Discussion on the Results

Numerical and predicted E_I/m and the relative percentage differences between them (ε) are listed in Tables B.1 and B.2 and also visualized in Figures B.1, B.2, B.3, B.4 and B.5 for the set of five model frames. In order to comment on the results, arithmetic means of ε were calculated. Arithmetic mean was calculated by summing up ε values and dividing by n , where n is the number of ε values used.

It can be observed from these results that the methodology proposed in this study gives better output for ordinary type (with far-fault characteristics and lower PGV) earthquake records in terms of predicting the input energy for $MDOF$ systems.

Using the suggested method in this study, for the set of 92 earthquake records on *Manoukas 3-St RC* frame, arithmetic mean of ε_{EI} was calculated as 38.6%. The correlation coefficient was calculated as 0.739, indicating a strong correlation, Figure 3.4.

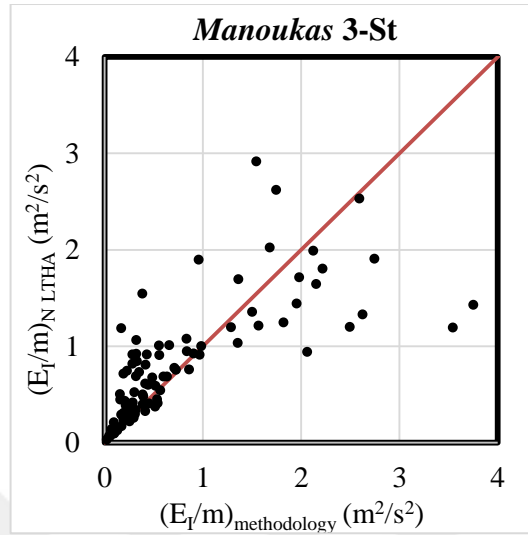

Figure 3.4 : Correlation between the estimated and numerical E_I/m for the set of 92 EQ records on RC frame.

For 35 EQ records with a $PGV \leq 50$ cm/s on *Manoukas 3-St*, arithmetic mean of ε_{EI} was calculated as 18.7%. The correlation coefficient was calculated as 0.961, indicating a very strong correlation, Figure 3.5.

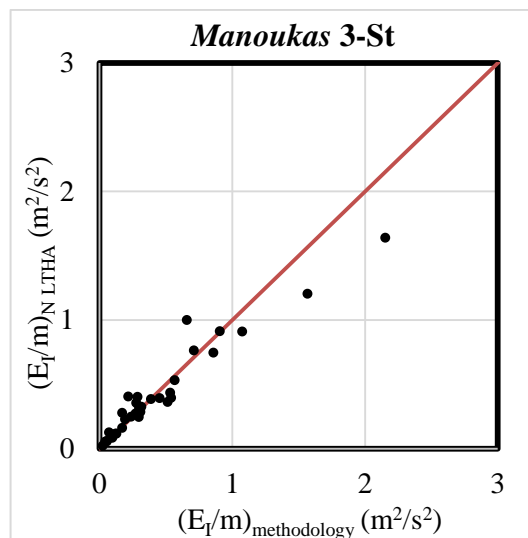

Figure 3.5 : Correlation between the estimated and numerical E_I/m for the EQ records with a $PGV \leq 50$ cm/s on RC frame.

Using the suggested method in this study, for the set of 92 earthquake records on *Akbas* 3-St, *Akbas* 6-St, *SAC-LA* 9-St, and *SAC-LA* 20-St steel frames, arithmetic means of ϵ_{EI} were calculated as 11.3%, 13.6%, 11.7%, and 13.9%, respectively.

The correlation coefficients for the steel frames examined in this study were calculated as 0.974, 0.932, 0.959, and 0.914, respectively. These results represent that there is a very strong correlation between the estimated and numerical input energies, Figure 3.6.

Figure 3.6 : Correlation between the estimated and numerical E_I/m for the set of 92 *EQ* records on steel frames.

Using the suggested method in this study, for 35 EQ records with a $PGV \leq 50$ cm/s on *Akbas* 3-St, *Akbas* 6-St, *SAC-LA* 9-St, and *SAC-LA* 20-St steel frames, arithmetic means of ε_{EI} were calculated as 5.8%, 7.7%, 6.0%, and 9.3%, respectively.

The correlation coefficients for the steel frames examined in this study were calculated as 0.994, 0.986, 0.990, and 0.948, respectively. These results represent that there is a very strong correlation between the estimated and numerical input energies, Figure 3.7.

Figure 3.7 : Correlation between the estimated and numerical E_I/m for the EQ records with a $PGV \leq 50$ cm/s on steel frames.

Distribution of the relative percentage differences between mass-normalized input energies calculated with the suggested method and “true” mass-normalized input energies obtained using Perform 3D with respect to 35 EQ records with a $PGV \leq 50$ cm/s are shown in Figure 3.8.

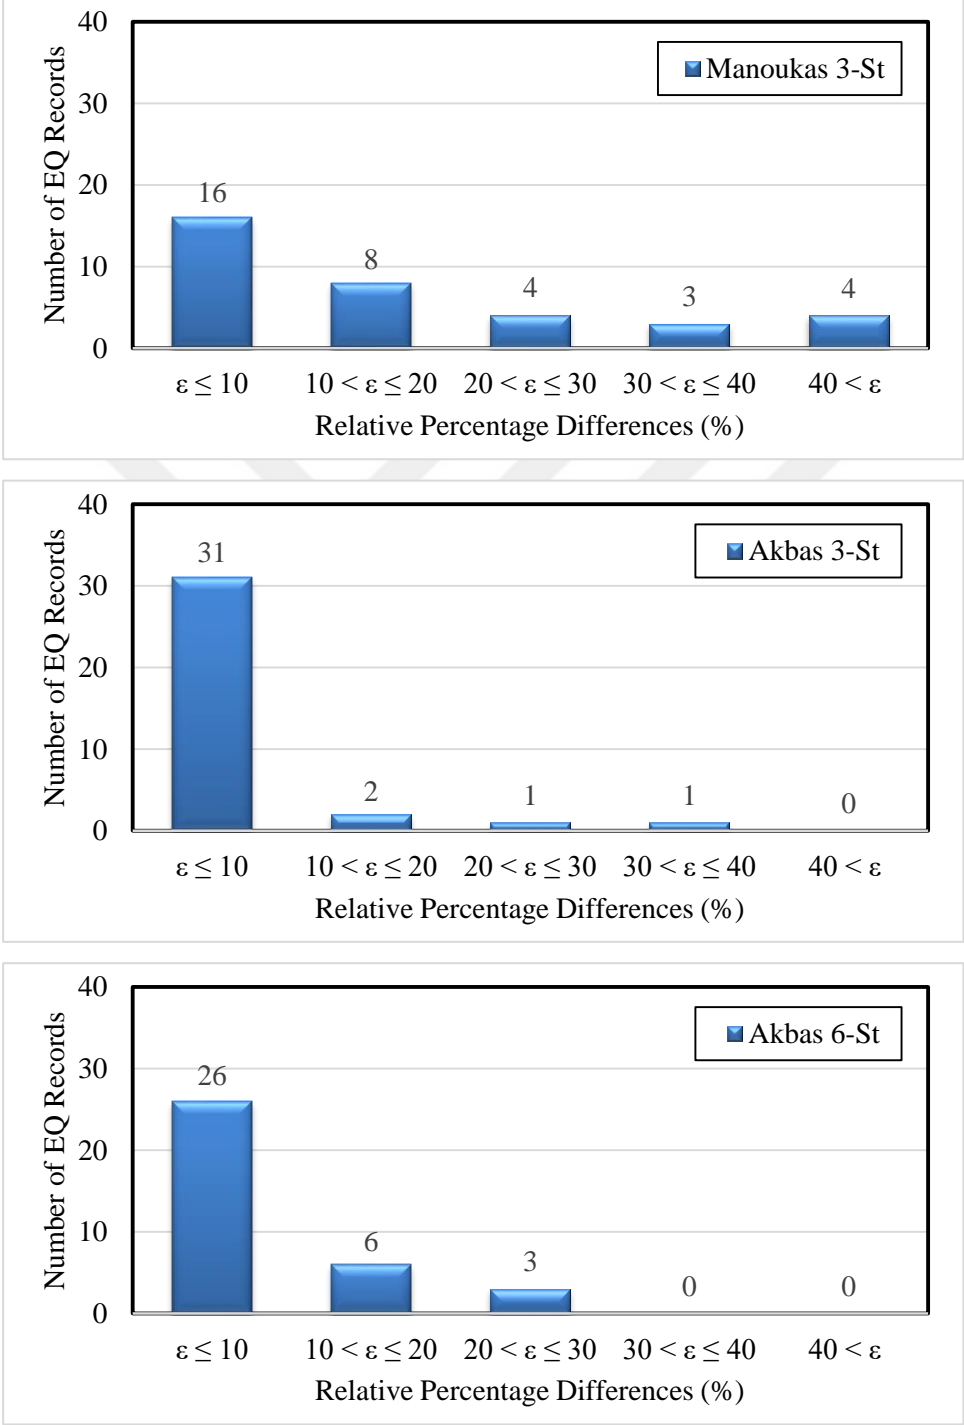

Figure 3.8 : Relative percentage difference distribution for E_1/m estimation.

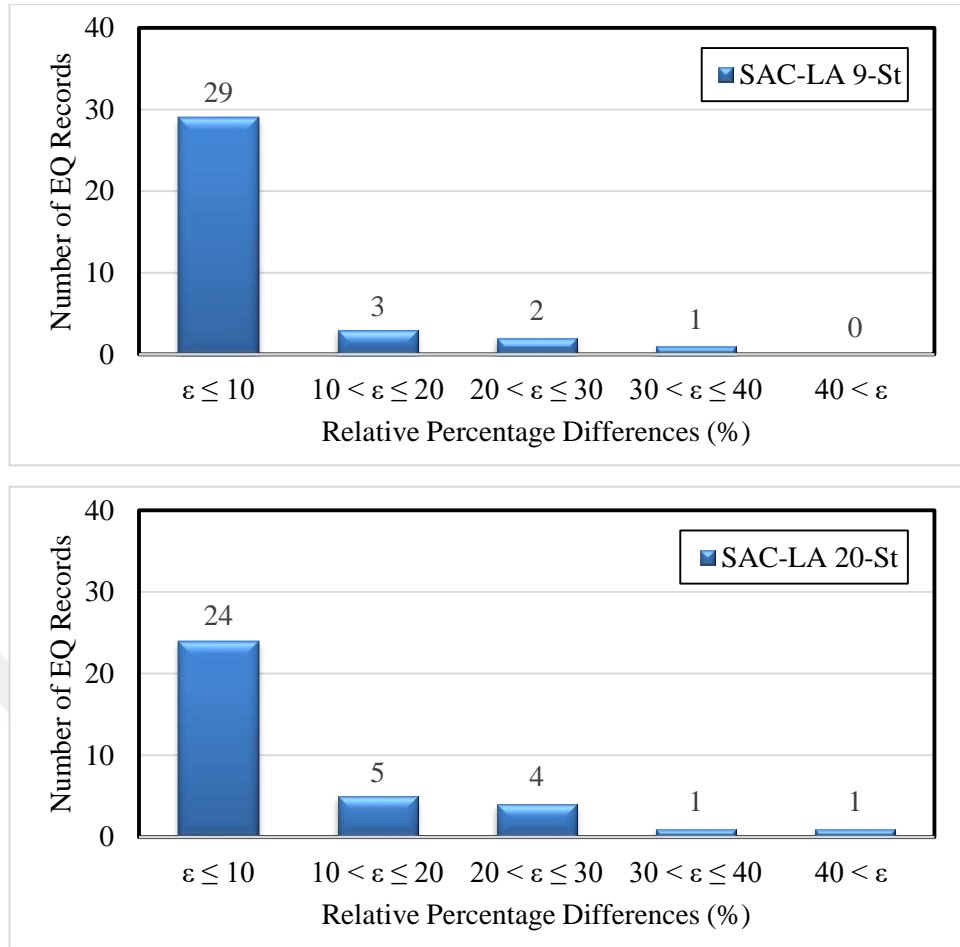

Figure 3.8 (continued) : Relative percentage difference distribution for E_I/m estimation.

3.4 Comparison with Other Methods in the Literature

3.4.1 Method proposed by Kalkan and Kunnath (2007)

For the estimation of the input energy for $MDOF$ systems, Kalkan and Kunnath (2007) suggested a formula where input energies calculated for E - $SDOF$ systems (Figure 3.9) are combined using the modal participation factor (Γ). In general, it can be estimated using up to the first three modes, equation (3.3).

In case the mode vectors are not normalized ($M_i^* \neq 1$), equation (3.3) becomes identical with equation (3.4) (Ucar, 2020).

$$E_{I(MDOF)} = \sum_{i=1}^n E_{I(E-SDOF)_i} \cdot \Gamma_i^2 \quad (3.3)$$

$$E_{I(MDOF)} = \sum_{i=1}^n E_{I(E-SDOF)_i} \cdot M_i^* \quad (3.4)$$

Figure 3.9 : “*n*” number of *E-SDOF* systems of a *MDOF* system.

Here, the time histories of input energy for *E-SDOF* systems are calculated using equation (1.9).

Using the method proposed by Kalkan and Kunnath (2007), for the set of 92 earthquake records on *Manoukas 3-St*, *Akbas 3-St*, *Akbas 6-St*, *SAC-LA 9-St*, and *SAC-LA 20-St* frames, arithmetic means of ε_{EI} were calculated as 39.2%, 11.7%, 12.8%, 13.2%, and 21.1%, respectively.

3.4.2 Method proposed by Güllü (2018)

Instead of using *E-SDOF* systems, Güllü (2018) proposed a method to estimate the seismic input energy for a *MDOF* system using the spectrum constructed for a *SDOF* system by equation (1.9). In this method, mass-normalized input energies (E_I / m) corresponding to an adequate number of vibrational modes of the structure are multiplied with the modal participation factors (Γ_j), equation (3.5).

$$(E_I / m)_{MDOF} = \frac{\sum_{j=1}^N (E_I / m)_j \cdot \Gamma_j}{\sum_{j=1}^N \Gamma_j} \quad (3.5)$$

Using the method proposed by Güllü (2018), for the set of 92 earthquake records on *Manoukas 3-St*, *Akbas 3-St*, *Akbas 6-St*, *SAC-LA 9-St*, and *SAC-LA 20-St* frames,

arithmetic means of ε_{EI} were calculated as 55.1%, 19.7%, 20.1%, 20.8%, and 32.7%, respectively.

It shows that the proposed method in this study gives better results than the ones Kalkan and Kunnath (2007) and Güllü (2018) suggested in terms of making a prediction about the total input energy in *MDOF* systems, especially for the frames with high number of stories, Table 3.1.

Table 3.1 : Comparison for arithmetic means of ε_{EI} (%).

Methodology	<i>Manoukas</i> 3-St	<i>Akbas</i> 3-St	<i>Akbas</i> 6-St	<i>SAC-LA</i> 9-St	<i>SAC-LA</i> 20-St
Kalkan and Kunnath (2007)	39.2	11.7	12.8	13.2	21.1
Güllü (2018)	55.1	19.7	20.1	20.8	32.7
This study	38.6	11.3	13.6	11.7	13.9

4. SEISMIC INPUT ENERGY DISTRIBUTION AMONG STORIES

Since the damage potential of an earthquake is directly dependent on the maximum dissipated hysteretic energy demand, estimation of it for a *MDOF* system is a crucial work for *EBSD*. In the literature, calculation of the dissipated hysteretic energy (E_H) and the distribution of it among stories have been the main focus of interest (Decanini et al. 2001, Chou and Uang 2003, Wang and Yi 2012, Mezgebo and Lui 2017, etc.). Structural properties (mass, modal shape, etc.) were generally used in order to distribute E_H among stories. Thus, a single E_H distribution pattern for each *MDOF* system (independent of the earthquake records) was obtained using these proposed methods.

4.1 Suggested Method to Estimate the Input Energy Distribution Pattern

This study follows a different approach and focuses on the prediction of E_I distribution pattern unlike the current methodologies in the literature focusing on the prediction of E_H distribution pattern. The formulation suggested in the previous chapter to predict the total input energy demand for a *MDOF* system (equation (3.1)) is modified here in order to predict the input energy demand in each story level, equation (4.1). Since there exists an earthquake-dependent term of $(E_I/m)_j$ in this equation (mass-normalized input energy values corresponding to each mode on the input energy spectra), it results in an E_I distribution pattern specific to each earthquake record. When E_H / E_I ratio is known, E_H distribution pattern can also be predicted with a high accuracy in the further studies.

$$(E_I)_i = \frac{\sum_{j=1}^N \phi_{ij} \cdot (E_I/m)_j \cdot \Gamma_j}{\sum_{j=1}^N \sum_{i=1}^n \phi_{ij} \cdot \Gamma_j} \cdot m_{total} \quad (4.1)$$

4.2 Numerical Calculation of the Seismic Input Energy Distribution

Since the distribution of the seismic input energy among the stories cannot be taken from Perform 3D software directly, it was calculated via a MATLAB-based code.

First, the time series of velocity responses (\dot{u}) at each story level with respect to the reference point (ground level) were taken from Perform 3D after nonlinear time history analyses were performed for each earthquake record in five model frames, Figure 4.1.

After velocity responses are calculated at each story level, input energy distribution among stories can be calculated using either equation (4.2) or equation (4.3). Since the mass matrix ($[M]$) of the frame type structures with lateral degrees of freedom only is a diagonal matrix, they both give the same result.

Figure 4.1 : An example for obtaining velocity responses at each story level.

$$\{E_I\} = -[M] \int_0^t \ddot{u}_g \{\dot{u}\} dt \quad (4.2)$$

$$E_{I,i} = -m_i \int_0^t \ddot{u}_g \dot{u}_i dt \quad (4.3)$$

It was observed that as the story level increases, input energy per unit mass imparted into the story tends to increase due to higher velocity responses. When the input energy time series for all stories numerically calculated using the MATLAB-based code were summed up, a value almost equal to the total E_I value read from Perform 3D was obtained, Figure 4.2.

Figure 4.2 : An example for input energy time history at story levels.

Peak values of the input energy time series were calculated for all 92 earthquake records in each story level of five model frames. Their distribution is shown in Figures 4.3, 4.4, 4.5, 4.6 and 4.7. Figures prove that it is not possible to represent the input energy distribution among stories with a single pattern regardless of the earthquake characteristics.

Figure 4.3 : E_I distribution of *Manoukas* 3-St for 92 EQ records.

Figure 4.4 : E_I distribution of Akbas 3-St for 92 EQ records.

Figure 4.5 : E_I distribution of Akbas 6-St for 92 EQ records.

Figure 4.6 : E_1 distribution of SAC-LA 9-St for 92 EQ records.

Figure 4.7 : E_I distribution of SAC-LA 20-St for 92 EQ records.

4.3 Discussion on the Results

Arithmetic means of ε for E_I predictions on story levels using 92 *EQ* records were calculated as 37.04%, 15.4%, 16.9%, 16.5%, and 29.4% for *Manoukas* 3-St, *Akbas* 3-St, *Akbas* 6-St, *SAC-LA* 9-St, and *SAC-LA* 20-St frames, respectively, Table 4.1.

Table 4.1 : Arithmetic means of relative percentage differences for input energy predictions on story levels using 92 *EQ* records.

Story #	<i>Manoukas</i> 3-St	<i>Akbas</i> 3-St	<i>Akbas</i> 6-St	<i>SAC-LA</i> 9-St	<i>SAC-LA</i> 20-St

Mean	18.7	13.1	12.3	10.1	19.3

It can be observed from the result that the relative percentage differences between the numerical and estimated story input energies are higher for the *RC* frame (*Manoukas 3-St*) and twenty-story steel frame (*SAC-LA 20-St*). Yet, it can be said that the methodology results in story input energies with an acceptable level of accuracy for the case of far-fault motion ($PGV \leq 50$ cm/s).

5. INELASTIC TOP DISPLACEMENT DEMAND PREDICTION

For some general nonlinear static analysis procedures, it is vital to predict the inelastic top displacement demand of a *MDOF* system with an error as low as possible. With this thesis study, an alternative for the calculation of the maximum inelastic top displacement according to the *equal displacement rule* will be proposed.

Maximum inelastic top displacement of a *MDOF* system during an earthquake can be predicted using the estimated seismic input energy with an acceptable accuracy.

5.1 Suggested Method to Estimate the Inelastic Top Displacement Demand

In a *MDOF* system, the dynamic response can be represented with a reference period (T_{ref}) which is calculated by combining the effects of sufficient number of modes as suggested by Marasco and Cimellaro (2018), equation (5.1).

$$T_{ref} = \frac{\sum_{j=1}^N T_j \times |\Gamma_j|}{\sum_{j=1}^N |\Gamma_j|} \quad (5.1)$$

Relation between input energy and top displacement for a *MDOF* system, which was first introduced by Mollaioli et al. (2011), is modified in the suggested method for the prediction of the top displacement, equation (5.2). Here, E_I/m is the mass-normalized input energy estimated in Chapter 3 and ω_{ref} is the angular frequency corresponding to T_{ref} , equation (5.3). Instead of using the ω of the first vibrational mode, ω_{ref} is used in order to take other mode effects into account. A new parameter (β) is defined with the equation (5.3) and its change with respect to T_1 is shown in Figure 5.1. T_{ref} and ω_{ref} values calculated for the model frames are listed in Table 5.1.

$$\delta_{top} = \frac{\sqrt{E_I/m}}{\beta \times \omega_{ref}} \quad (5.2)$$

$$\beta = \begin{cases} 1.5 - T_1; & T_1 < 0.75s \\ 0.75; & T_1 \geq 0.75s \end{cases} \quad (5.3)$$

Figure 5.1 : Suggested bilinear β spectra.

Table 5.1 : Calculated reference periods and angular frequencies.

Frame	T_{ref} (s)	ω_{ref} (rad)
<i>Manoukas 3-St</i>	0.41	15.32
<i>Akbas 3-St</i>	0.67	9.38
<i>Akbas 6-St</i>	1.15	5.46
<i>SAC-LA 9-St</i>	1.70	3.70
<i>SAC-LA 20-St</i>	2.82	2.23

Second degree parabolic relation is obtained between input energy and top displacement for the set of five model frames used in this study, Figure 5.2.

Figure 5.2 : Input energy – top displacement relationship.

Inelastic top displacement demand predictions ($(\delta_{top})_{pre}$) were made using the suggested method in this study, equation (5.2). After that, they were compared with

the numerical results obtained after running nonlinear time history analysis in Perform 3D software $((\delta_{top})_{num})$. The relative percentage differences between the predictions and numerical results (ε_{EI}) were calculated using equation (5.4).

$$\varepsilon_{\delta} = \frac{|\delta_{top,pre} - \delta_{top,num}|}{\frac{[\delta_{top,pre} + \delta_{top,num}]}{2}} \quad (5.4)$$

With the proposed method, an accurate relation between mass-normalized input energy and inelastic top displacement demand of a MDOF system is obtained. The comparison of the relation obtained by the suggested method and Perform 3D results of 92 earthquake records are shown in Figure 5.3.

Figure 5.3 : Comparison for input energy – top displacement relation for the set of 92 EQ records on steel frames.

The comparison of the relation obtained by the suggested method and Perform 3D results for the *EQ* records with a $PGV \leq 50$ cm/s are shown in Figure 5.4.

Figure 5.4 : Comparison for input energy – top displacement relation for the *EQ* records with a $PGV \leq 50$ cm/s on steel frames.

5.2 Discussion on the Results

Numerical and predicted inelastic top displacement demands and the relative percentage differences between them are listed in Tables C.1 and C.2 and also visualized in Figures C.1, C.2, C.3, C.4 and C.5 for the set of five model frames. Like E_I/m estimations in the previous chapter, it can be observed that the methodology proposed in this study gives better results for ordinary type (far fault characteristics and lower PGV) earthquake records in terms of predicting the displacement demand of *MDOF* systems.

Using the suggested method in this study, for the set of 92 earthquake records on *Manoukas 3-St RC* frame, arithmetic mean of ε_{EI} was calculated as 53.1%. The correlation coefficient was calculated as 0.546 indicating a moderate correlation, Figure 5.5.

Figure 5.5 : Correlation between the estimated and numerical δ_{top} for the set of 92 *EQ* records on *RC* frame.

For 35 *EQ* records with a $PGV \leq 50$ cm/s on *Manoukas 3-St*, arithmetic mean of ε_{EI} was calculated as 20.9%. The correlation coefficient was calculated as 0.866 indicating a very strong correlation, Figure 5.6.

Figure 5.6 : Correlation between the estimated and numerical δ_{top} for the *EQ* records with a $PGV \leq 50$ cm/s on *RC* frame.

Using the suggested method in this study, for the set of 92 earthquake records on *Akbas* 3-St, *Akbas* 6-St, *SAC-LA* 9-St, and *SAC-LA* 20-St steel frames, arithmetic means of ε_{δ} were calculated as 18.3%, 20.6%, 18.8%, and 20.9%, respectively.

The correlation coefficients for the steel frames examined in this study were calculated as 0.857, 0.849, 0.878, and 0.883, respectively. These results represent that there is a very strong correlation between the estimated and numerical inelastic top displacement demands of the selected *MDOF* systems, Figure 5.7.

Figure 5.7 : Correlation between the estimated and numerical δ_{top} for the set of 92 *EQ* records on steel frames.

Using the suggested method in this study, for 35 *EQ* records with a $PGV \leq 50$ cm/s on *Akbas* 3-St, *Akbas* 6-St, *SAC-LA* 9-St, and *SAC-LA* 20-St steel frames, arithmetic means of ε_s were calculated as 17.7%, 13.4%, 18.9%, and 16.4%, respectively.

The correlation coefficients for the steel frames examined in this study were calculated as 0.882, 0.917, 0.841, and 0.866, respectively. These results represent that there is a very strong correlation between the estimated and numerical inelastic top displacement demands of the selected *MDOF* systems, Figure 5.8.

Figure 5.8 : Correlation between the estimated and numerical δ_{top} for the *EQ* records with a $PGV \leq 50$ cm/s on steel frames.

Distribution of the relative percentage differences between top displacements calculated with the suggested method and “true” top displacements obtained using Perform 3D software with respect to 35 EQ records with a $PGV \leq 50$ cm/s are shown in Figure 5.9.

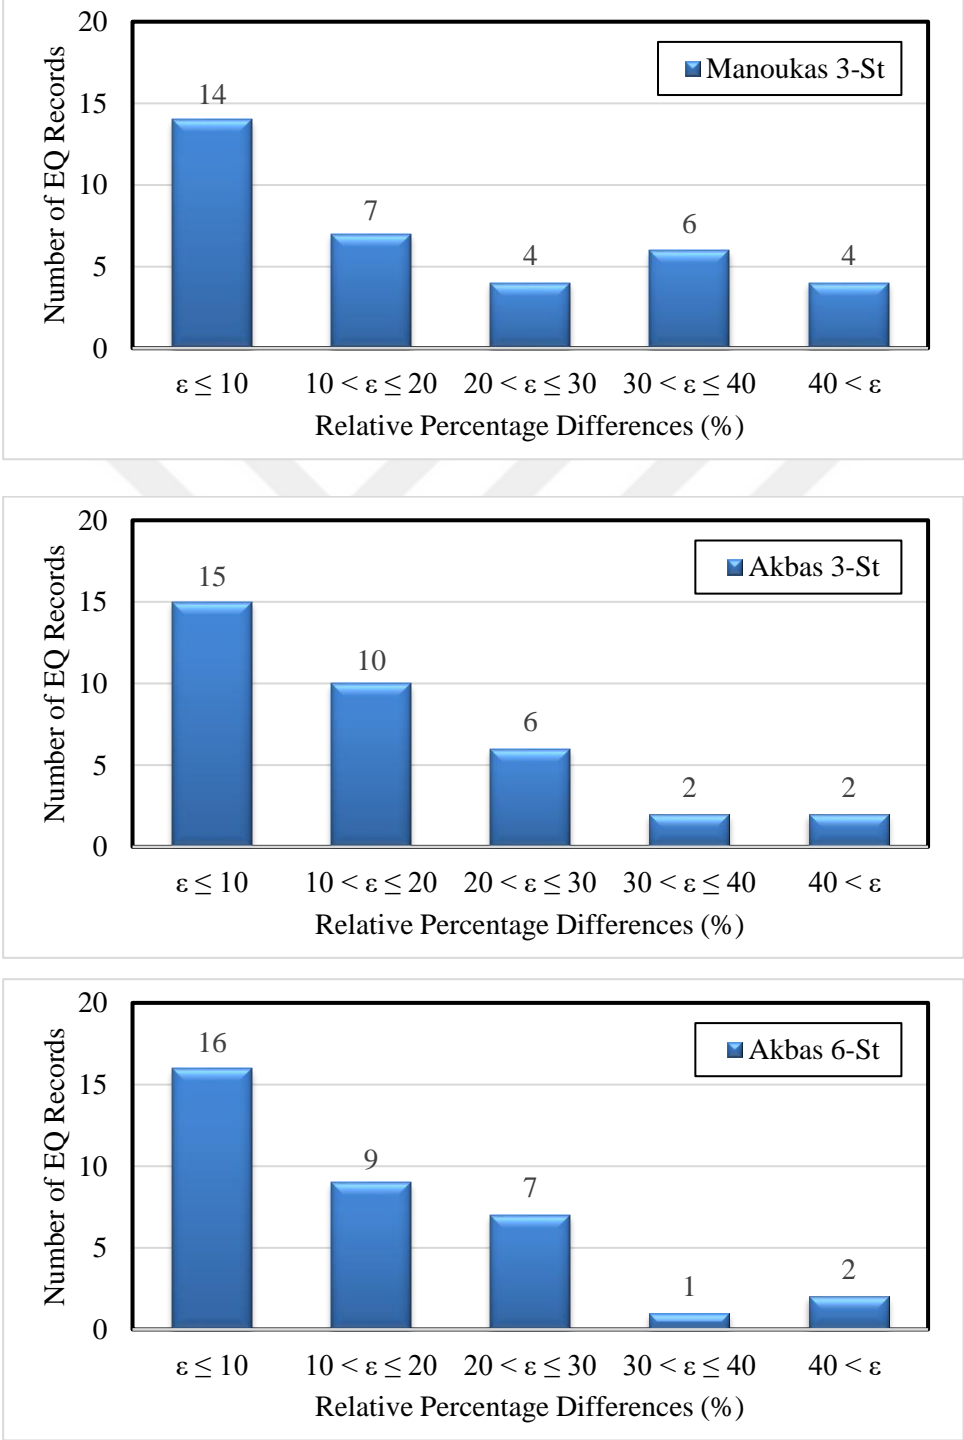

Figure 5.9 : Relative percentage difference distribution for δ_{top} estimation.

Figure 5.9 (continued) : Relative percentage difference distribution for δ_{top} estimation.

5.3 Comparison with Other Methods in the Literature

5.3.1 Method proposed by Manoukas et al. (2011)

An energy-based pushover procedure is suggested by Manoukas et al. (2011) in order to estimate the story displacements under an *EQ* record.

According to the suggested methodology, lateral incremental forces with a distribution pattern proportional to $M \cdot \Phi_I$ vector are applied to the created structural model as the first step. The strain energy-displacement curve ($E_I - u_{NI}$) is obtained where E_I is the work of external forces and u_{NI} stands for top displacement of the *MDOF* system. Then, the strain energy-displacement curve for the *E-SDOF* system ($E_I - D_I$) is calculated dividing u_{NI} value by the quantity $\Gamma_I \cdot \Phi_{NI}$. Using $E_I - D_I$ curve, the force-displacement curve for the *E-SDOF* system ($V_I - D_I$) is obtained. Story displacements are then calculated using displacement modification procedures.

In this study, story displacement predictions were made for $0.5 \times$ El Centro, $1.0 \times$ El Centro, and $1.5 \times$ El Centro and they were compared with the *NLTHA* results for the reinforced concrete *Manoukas 3-St* frame.

In order to make a comparison between the method proposed by Manoukas et al. (2011) and the methodology suggested in this study, seismic demands of Manoukas 3-St frame were estimated for El Centro record (Figure 5.10) with scales of 0.5, 1.0, 1.5 as well. First, mass-normalized input energy spectrum was constructed for *SDOF* systems, Figure 5.11.

Figure 5.10 : Ground acceleration for $1.0 \times$ El Centro.

Figure 5.11 : Mass-normalized input energy spectrum for $1.0 \times$ El Centro.

Using the suggested method, E_I/m values were calculated for *MDOF* system. Then, by using the suggested relationship between input energy and top displacement, inelastic

top displacement demands were predicted and a comparison was made between *NLTHA* results and the top displacement predictions, Table 5.2.

As it can be seen from the table, the methodology yields better top displacement prediction results than the method proposed by Manoukas et al. (2011) for $0.5 \times$ El Centro, $1.0 \times$ El Centro, and $1.5 \times$ El Centro records.

Table 5.2 : Comparison with Manoukas et al. (2011) for δ_{top} predictions.

<i>EQ</i>	$(\delta_{top})_{NLTHA}$ (cm)	Manoukas et al. (2011)		This study	
		$(\delta_{top})_{pre.}$ (cm)	ε_{δ} (%)	$(\delta_{top})_{pre.}$ (cm)	ε_{δ} (%)
$0.5 \times$ El Centro	2.988	3.656	20.1	3.944	27.6
$1.0 \times$ El Centro	5.627	5.697	1.2	5.577	0.9
$1.5 \times$ El Centro	7.803	11.076	34.7	6.831	13.3

5.3.2 Method proposed by Güllü (2018)

Güllü (2018) used the velocity spectra and displacement spectra to predict the relationship between seismic input energy and the top displacement demand of a *MDOF* moment resisting steel frame system.

A hybrid spectrum is constructed by an inclined line with a slope of “ α ” which is calculated using spectral velocity ($SV(T_1, \zeta)$) and displacement ($SD(T_1, \zeta)$) corresponding to the first mode and a variable “ n ” defining the relation between SV and (E_I/m) , equation (5.5). The value of the variable “ n ” is obtained from the equation of trendline of the graph and it varies between 0.5 and 2.0, Figure 5.12.

$$\alpha = \frac{SV(T_1, \xi)^2}{n \times SD(T_1, \xi)} \quad (5.5)$$

Spectral displacement (SD) is obtained from the hybrid spectrum (Figure 5.13) by drawing a vertical line from the point where horizontal line from estimated mass-normalized input energy value intersects with the inclined line with slope of “ α ”. After that, the physical top displacement of the *MDOF* system is calculated using equation (5.6).

$$u_{jn} = \sum_{j=1}^N \Gamma_j \cdot \phi_{jn} \cdot SD \quad (5.6)$$

Figure 5.12 : Relation between SV and (E_I / m) .

Figure 5.13 : Hybrid spectrum suggested by Güllü (2018).

After $(\delta_{top})_{pre}$ values were also calculated with the method proposed by Güllü (2018), they were compared with the “true” inelastic top displacement demands.

Using the method proposed by Güllü (2018), for the set of 92 earthquake records on *Akbas 3-St*, *Akbas 6-St*, *SAC-LA 9-St*, and *SAC-LA 20-St* frames, arithmetic means of ε_s were calculated as 41.3%, 37.8%, 41.7%, and 40.7%, respectively.

It shows that the proposed method in this study gives better results than the one Güllü (2018) suggested in terms of making a prediction about the top displacement demand in *MDOF* systems.

6. CONCLUSIONS AND RECOMMENDATIONS

In the content of this M.Sc. thesis study, a methodology to estimate the input energy distribution and inelastic top displacement demand of steel moment resisting frame type structures was suggested. Its verification was made by applying the methodology on four steel model frames with different story numbers and performing nonlinear time history analyses using 92 earthquake records.

In order to check the applicability of the methodology on reinforced concrete frames, the methodology developed for the steel frames was tested on an *RC* frame as well. Thus, the number of model frames used in the verification of the methodology was increased to five.

For the implementation of the proposed methodology, these steps are followed:

Step 1. Create the structural model and run the modal analysis.

Step 2. Decide how many vibrational modes to use.

Step 3. Calculate the mass-normalized input energy spectra using the relative input energy approach.

Step 4. Calculate the input energy on each story level using mode shape, modal participation factor, and E_I/m values corresponding to each mode on the input energy spectra, equation (4.1). By summing them up and dividing by the total mass of the structure, obtain the mass-normalized seismic input energy for the whole structure.

Step 5. Calculate the inelastic top displacement demand of the structure using the mass-normalized input energy of the whole structure, reference angular frequency, and a period-dependent coefficient, equation (5.2).

6.1 Conclusions

- Maximum mass-normalized input energies imparted into the *MDOF* systems were shown to be estimated fast and accurately by only using their modal properties and

seismic input energy spectrum created for *SDOF* systems. The suggested methodology produced a mean relative percentage difference of around 12% with the results of the *NLTHA* for the steel frames of three-, six-, nine- and twenty-stories.

- Input energy distribution among the stories of three-, six-, and nine-story steel frames were estimated with a mean relative percentage difference of around 15%. Yet, the methodology yielded less accurate results for input energy distribution on twenty-story frame even though total input energy estimation was precise enough. The reason of this might be that the input energy distribution is sensitive to higher mode effects. Thus, less accurate results were obtained as the number of stories increased.
- Maximum top displacements experienced by the *MDOF* systems during an earthquake excitation -which can be used as an input values in some general nonlinear static analysis procedures- were shown to be estimated accurately by using mass-normalized input energy, angular frequency corresponding to their reference period, and a suggested parameter called “ β ”. The suggested methodology produced a mean relative percentage difference of around 18% with the results of the *NLTHA* for the selected steel frames.
- For the set of all 92 *EQ* records applied on *Manoukas 3-St RC* frame, seismic demands were calculated with higher relative percentage differences, meaning less accuracy compared to the steel frames, Table 6.1. The reason of this might be that the suggested methodology loses its validity for the low-period structures: *Manoukas 3-St RC* frame has the lowest period ($T_1 = 0.51$ s) out of the selected model frames.

Table 6.1 : Arithmetic means of relative percentage differences for seismic demand predictions (using the set of all 92 records).

Frame	$(E_I/m)_{total}$	$(E_I/m)_{story}$	δ_{top}
<i>Manoukas 3-St</i>	38.6	37.0	53.1
<i>Akbas 3-St</i>	11.3	15.4	18.3
<i>Akbas 6-St</i>	13.6	16.9	20.6
<i>SAC-LA 9-St</i>	11.7	16.5	18.8
<i>SAC-LA 20-St</i>	13.9	29.4	20.9

- The methodology resulted in more accurate seismic input energy and nonlinear displacement demand values for earthquake records with a PGV value less than 50 m/s (ordinary non-pulse-like ground motions with the characteristics of far-fault earthquake excitation) used in the analyses, especially for *Manoukas* 3-St reinforced concrete frame.
- Using the EQ records with a $PGV \leq 50$ cm/s, it was observed that the methodology yields seismic demand components with acceptable approximation levels even though the relative percentage differences for EI/m estimation were computed slightly larger for the RC frame (*Manoukas* 3-St) in comparison with the steel frames (*Akbas* 3-St, *Akbas* 6-St, *SAC-LA* 9-St, and *SAC-LA* 20-St), Table 6.2.

Table 6.2 : Arithmetic means of relative percentage differences for seismic demand predictions (using the records with a $PGV \leq 50$ cm/s).

Frame	$(EI/m)_{total}$	$(EI/m)_{story}$	δ_{top}
<i>Manoukas</i> 3-St	17.1	18.7	20.9
<i>Akbas</i> 3-St	5.8	13.1	15.8
<i>Akbas</i> 6-St	7.7	12.3	14.8
<i>SAC-LA</i> 9-St	6.0	10.1	19.8
<i>SAC-LA</i> 20-St	9.3	19.3	18.8

- Effects of the number of modes used in the methodology was also investigated. It was observed that the methodology yields better results for the mass-normalized input energy predictions as the number of modes increases, Table 6.3.

However, no direct correlation between the number of modes and the inelastic top displacement demand predictions was observed, Table 6.4.

- The results obtained using the suggested methodology were compared with some other procedures existing in the literature. After EI/m imparted into the selected model frames in this study were predicted using the methods proposed by Kalkan and Kunnath (2007) and Güllü (2018) as well, a comparison between them and the methodology was made. In order to make a comparison for δ_{top} prediction, the method proposed by Güllü (2018) was applied to the model frames. Additionally, inelastic top displacements were predicted for the RC frame (*Manoukas* 3-St) using

the suggested methodology and compared with the predictions given in the study of Manoukas et al. (2011). It was observed that the methodology suggested in this study yields better results compared to the ones in the literature.

Table 6.3 : Effects of the number of modes used in the methodology for the seismic input energy predictions.

Frame	Arithmetic Means of Relative Percentage Differences (%)				
	First Mode	First 2 Modes	First 3 Modes	First 4 Modes	First 5 Modes
<i>Manoukas 3-St</i>	39.6	38.6	37.9	-	-
<i>Akbas 3-St</i>	16.4	11.3	11.2	-	-
<i>Akbas 6-St</i>	21.0	15.8	13.6	13.2	12.9
<i>SAC-LA9-St</i>	22.1	12.9	11.7	11.1	11.0
<i>SAC-LA20-St</i>	33.5	16.8	13.9	12.8	12.3

Table 6.4 : Effects of the number of modes used in the methodology for the inelastic top displacement demand predictions.

Frame	Arithmetic Means of Relative Percentage Differences (%)				
	First Mode	First 2 Modes	First 3 Modes	First 4 Modes	First 5 Modes
<i>Manoukas 3-St</i>	53.6	53.1	51.1	-	-
<i>Akbas 3-St</i>	18.6	18.3	18.4	-	-
<i>Akbas 6-St</i>	20.2	20.1	20.6	20.7	20.9
<i>SAC-LA9-St</i>	20.1	18.4	18.8	19.0	19.1
<i>SAC-LA20-St</i>	20.4	20.5	20.9	20.4	21.6

6.2 Recommendations

- The applicability of the methodology should be studied on different frame types (such as braced frames).
- The proposed methodology in this study should be extended for mid-rise and high-rise reinforced concrete frames as well.
- The methodology should be taken a step further by eliminating the negative effects of pulse-like seismic excitations on the methodology.

91	0.305	0.303	0.6	0.451	0.297	41.2
92	0.243	0.148	48.4	0.313	0.202	42.9
Ar. Mean		18.8			20.9	
Geo. Mean		12.0			12.9	
Correlation		0.878			0.883	

Figure C.1 : δ_{top} comparison between methodology and *NLTHA* for *Manoukas* 3-St frame using the EQ records with a $PGV \leq 50$ cm/s.

Figure C.2 : δ_{top} comparison between methodology and *NLTHA* for *Akbas* 3-St frame using the EQ records with a $PGV \leq 50$ cm/s.

Figure C.3 : δ_{top} comparison between methodology and *NLTHA* for *Akbas* 6-St frame using the EQ records with a $PGV \leq 50$ cm/s.

Figure C.4 : δ_{top} comparison between methodology and *NLTHA* for *SAC-LA* 9-St frame using the EQ records with a $PGV \leq 50$ cm/s.

Figure C.5 : δ_{top} comparison between methodology and *NLTHA* for SAC-LA 20-St frame using the EQ records with a PGV ≤ 50 cm/s.

CURRICULUM VITAE

Name Surname : Furkan ÇALIM
Place and Date of Birth : Istanbul / 07.11.1995
E-Mail : furkancalim05@gmail.com

EDUCATION :

- **B.Sc.** : 2018, Istanbul Technical University, Faculty of Civil Engineering, Civil Engineering Department

PROFESSIONAL EXPERIENCE AND REWARDS:

- 2019- Research Assistant at Civil Engineering Department of ITU.
- 19.09.2019 Structural Dynamics Workshop Hackathon (Izmir Institute of Technology) – 1st Place Reward
- 01.07.2020 Graduate Research Poster Day (Istanbul Technical University) – 2nd Place Reward
