**Date of Submission : 02 May 2016**  
**Date of Defense : 09 June 2016**

## **FOREWORD**

Special thanks to Prof. Dr. Cellaletdin Ergun for his support and guidance and I thank him for all the things that he thought me during this two years. I also thank all my friends and our research group members, Selim Parlak and Elvan Aydın.

June 2016

Mona NEJATPOUR  
Mechanical Engineer

## **ABBREVIATIONS**

AC	: Alternating current
APTES	: (3-Aminopropyl)triethoxysilane
DI	: Deionised
FTIR	: Fourier transform infrared spectroscopy
MNP	: Magnetic nanoparticle
MRI	: Magnetic resonance imaging
NP	: Nanoparticle
PEG	: Polyethylene glycol
SEM	: Scanning electron microscope
SPION	: Superparamagnetic iron oxide nanoparticles
TEOS	: Tetraethyl orthosilicate
VSM	: Vibrating sample magnetometer

## SYMBOLS

<b>B</b>	: Magnetic induction
<b>H</b>	: Magnetic field strength
<b>H<sub>apply</sub></b>	: Strength of applied AC magnetic field
<b>K</b>	: Anisotropy constant
<b>M</b>	: Magnetic moment per volume
<b>P</b>	: Heat dissipation
<b>T</b>	: Temperature
<b>V<sub>H</sub></b>	: Hydrodynamic particle volume
<b>V<sub>M</sub></b>	: Volume of particle
<b>Z</b>	: Viscosity
<b>f</b>	: AC magnetic field frequency
<b>k</b>	: Boltzmann constant
<b>μ<sub>0</sub></b>	: Permeability in vacuum
<b>χ</b>	: Volumetric magnetic susceptibility
<b>χ''</b>	: AC magnetic susceptibility (imaginary part)
<b>τ</b>	: Effective magnetic relaxation time
<b>τ<sub>B</sub></b>	: Brownian magnetic relaxation time
<b>τ<sub>N</sub></b>	: Neel magnetic relaxation time

## SYNTHESIZE AND CHARACTERIZATION OF MULTI-COMPONENT MAGNETIC NANO PARTICLES

### SUMMARY

Magnetic nanoparticles are a major class of nonscale materials. Because of their unique properties and ability to function at the cellular and molecular level they have a potential to provide significant improvements in healthcare. They are actively investigated as magnetic resonance imaging contrast agents and carriers for targeted drug delivery.

According to some researches cancer is the third leading cause of death in developed countries. The traditional treatments for cancer are surgery, radiation and chemotherapy each bears the risk of killing healthy cells and fatally damaging healthy tissues along with the infected region. The new techniques being researched aims to target only the infected site with molecular drugs and nanoparticles are considered as the carriers.

At the core of nanotherapeutic agent design is the determination of materials and techniques to make the nanoparticles biocompatible. For this purpose firstly nanoparticles are coated with oleic acid to prevent oxidization. The next step is to prevent agglomeration and this is provided by silica coating. After that nanoparticles are prepared for gold coating with amination and coated with gold so that nanoparticles become nontoxic. The last step is polymer coating to make nanoparticles organic.

In this project five different magnetic nanoparticles have been synthesized in room temperature.  $Fe_3O_4$ ,  $MgFe_2O_4$ ,  $MnFe_2O_4$ ,  $SrFe_{12}O_{19}$  and  $BaFe_{12}O_{19}$  samples have been synthesized in different sizes while magnetic core size have been chosen in a way that they are in a size range to be biocompatible for magnetic nanoparticle hyperthermia. Different core sizes have been achieved by changing pH and added water ratio while using precipitation method. Three different pH values and three different concentrations have been used.

After synthesizing magnetic nanoparticle cores a specific amount of the nanoparticles has been coated with silica by Stöber method and a specific amount of silica coated samples has been ammoniated. As a side note  $Fe_3O_4$  cores have been coated with oleic acid during the core synthesizing process to prevent oxidization.

FTIR analyses of the produced samples have shown Fe-O, Fe-O-Fe, Mg-O, Mn-O, Sr-O, Ba-O, Mg-Fe, Mn-Fe, Sr-Fe and Ba-Fe bonds which confirm the nanoparticles have been produced correctly; Fe-COOO, H-C-H and C-O bonds which shows the existence of oleic acid coating; Si-O, Si-O-Si and Fe-O-Si bonds which sign silica coating and O-H and N-H bonds which confirm amination.

In SEM analysis the structures and particle sizes are investigated. Effects of pH and concentration on particle sizes are determined.

## **ÇOK BİLEŞENLİ MANYETİK NANO PARÇACIK SENTEZİ VE KARAKTERİZASYONU**

### **ÖZET**

Manyetik nanoparçacıklar nano ölçekli malzemelerin mevcut klinik tanı ve tedavi tekniklerinde devrim yaratabilecek potansiele sahip önemli bir sınıftır. Manyetik nanoparçacıklar özgün özellikleri ve hücresel ve molekül düzeydeki biyolojik etkileşimlerde işlevsel olabilme kabiliyetleri sebebiyle yeni nesil manyetik rezonans görüntüleme (MRI) kontrast maddesi ve hedeflenen ilaç sisteminin taşıyıcıları olarak aktif şekilde incelenmektedirler.

Bu alandaki ilk çalışmalar birkaç on yıl geçmişe tarihlenebilse de yakın geçmişte nanoteknolojiye olan ilgiye artışı manyetik nanoparçacık araştırmalarının alanını ve derinliğini önemli derecede genişletmiştir. Kanser, kardiyovasküler rahatsızlıklar ve nörolojik rahatsızlıklar gibi hastalıkların tespit, tanı ve tedavisinde geniş yelpazeli uygulamalarıyla manyetik nanoparçacıklar yakında geleceğin sağlık ihtiyaçlarını karşılamada önemli bir rol oynayabilirler.

Kanser ölüm sebepleri arasında gelişmiş ülkelerde kalp rahatsızlıkları ve inmenin ardından üçüncü Amerika Birleşik Devletleri'nde kalp rahatsızlıklarının ardından ikincidir. Kanser geleneksel olarak ameliyat, radyoterapi ve kemoterapi ile tedavi edilir. Bu yaklaşımların tamamı sağlıklı hücreleri öldürme ve sağlıklı dokulara ölümcül bir şekilde hasar verme riski taşır. Nanoteknolojinin ortaya çıkması ve hızla yükselmesiyle nanomalzemeler küçük moleküler ilaçların ve biyolojik ajanların taşınmasına yardım ederek yeni fırsatlar sunmaktadır. Bu tarz maddelerin nanomalzemelerle taşınmasıyla yapılacak tedaviler ilacın hedeflenen yere etki etmesini ve sağlıklı dokuların tedaviden etkilenmesinin sınırlandırılması sağlayacaktır.

Nanotedavi ajanının tasarlanmasının merkezinde canlı içerisindeki malzeme akışı, izlenebilirlik ve tedavisel işlev konularındaki sıkı gereksinimleri karşılayan son ürünün oluşturulmasında kullanılabilecek malzeme ve tekniklerin belirlenmesi yer alır. Nanotedavi ajanının içeriğindeki malzemeler hedeflenen işlevlerini gerçekleştirebilirken aynı zamanda, bozunma sonucu ortaya çıkacak malzemeler de göz önünde bulundurularak, biyolojik olarak uyumlu olacak şekilde seçilirler. Bahsi geçen malzemeler biyolojik sistemlerle de etkileşeceği için bu süreç karmaşık olabilir.

Nanoparçacıkların biyolojik olarak uyumlu olması amacıyla birtakım kaplama işlemleri uygulanmaktadır. Nanoparçacıkların okside olmaması için oleik asitle kaplama yapılmaktadır. Parçacıkların yığılarak büyümesinin önlenmesi için silika kaplama uygulanmaktadır. Nanoparçacıkların toksik olmayan hale gelmesi için altın kaplama uygulanmakta fakat bunun yapılabilmesi için öncelikle silika kaplamadan sonra amünasyon işlemi gerçekleştirilmektedir. Altın kaplamanın ardından elde edilen nanoparçacığın organik olması için son adım olarak polimer kaplama yapılmaktadır.

Bu çalışmada oda sıcaklığında, farklı boyutlarda medikal olarak kullanılma potansiyeli olan beş farklı manyetik nanoparçacık çökeltme metoduyla sentezlenmiştir. Bunlar  $Fe_3O_4$ ,  $MgFe_2O_4$ ,  $MnFe_2O_4$ ,  $SrFe_{12}O_{19}$  ve  $BaFe_{12}O_{19}$ 'dur. Sentezlenen malzemelerin manyetik çekirdek boyutları manyetik nanoparçacık hipertermisi için biyolojik olarak uyumlu olacak aralıkta bulunacak şekilde seçilmiştir. Farklı çekirdek boyutları pH ve su oranının değiştirilmesiyle elde edilmiştir. Çökeltme metodu uygulanırken üç farklı konsantrasyon ve üç farklı pH değeri kullanılmıştır. Böylece dokuz farklı boyutta çekirdek elde edilmeye çalışılmıştır.

İlk olarak her bir tür nanoparçacıktan üçer gram sentezlenmiştir. FTIR analizinin ardından nanoparçacıkların yapısından emin olunduktan sonra herbir nanopartikül türünden, reaksiyon formüllerine göre, katalizör olarak NaOH kullanılarak yirmişer gram sentezlenmiştir. Sentezlenen malzemelere bakıldığında  $Fe_3O_4$  numunelerinin oksitlendiği görülmüştür. Bu nedenle  $Fe_3O_4$  sentezlenirken sentezleme aşamasında oleik asitle kaplama yapılmasına karar verilmiştir.  $Fe_3O_4$  nanoparçacıkları için gram başına uygun olan oleik asit miktarı belirlendikten sonra sentezlemeye oleik asit de dahil edilmiştir. Sonuçta bazı deneysel şartlar başarısız olmuş ve 44 adet çekirdek numunesi elde edilmiştir. Elde edilen numunelerin üçer gramı ayrılmış ve geri kalanları yüzey kaplama için şişelerde depolanmıştır.

Bir sonraki adımda depolanmış olan manyetik nanopartiküller Stöber yöntemi kullanılarak silika ile kaplanmıştır. TEOS miktarı değiştirilerek 4 ile 6 nm arasında kaplama kalınlığı elde edilmiştir.

Silika kaplamadan sonra silika ile kaplanmış olan numunelerin üçer gramı ayrılmış ve geri kalanları altın ve PEG kaplama için amünasyona tabi tutulmuştur. Bu işlemde sonra yine üçer gram numune ayrılmış ve geri kalanlar altın ve PEG kaplama için şişelerde depolanmıştır.

Bu işlemlerin ardından çekirdek, silika kaplı ve amünasyona tabi tutulmuş, farklı boyutlarda, farklı malzemelerden oluşan 132 numune elde edilmiştir. Sonrasında her numuneden birer gram FTIR, VSM ve XRD analizlerinde kullanılmak üzere 8-9 saat su banyosunda tutularak kurutulmuş ve vakum pompaları kullanılarak otuzar dakika vakum ortamında tutulmuştur. SEM ile nanoparçacıkların boyutlarının ölçülmesinde ise numunelerin çözelti halleri kullanılmıştır.

FTIR analizinde dalga boylarına ve bantlara bakılarak malzeme karakteristikleri incelenmiş ve manyetik nanoparçacıkların doğru bir şekilde sentezlendiği görülmüştür. Yine aynı analizlerde silika kaplama ve amünasyon işlemlerinin de doğru bir şekilde yapıldığı gözlemlenmiştir. Bu çalışmada elde edilen nanopartiküller ferro akışkanlar olarak adlandırılmakta ve Fe bantları (Fe-O ve Fe-O-Fe) 500-600  $cm^{-1}$  aralığında olmalıdır. Yapılan FTIR analizlerinde 540 ile 570  $cm^{-1}$  aralığındaki değerler gözlemlenmiştir. Bu değerler Fe-O ve Fe-O-Fe bantlarının varlığını göstermektedir. Bunun dışında elde edilen nanoparçacıkların birbirinden farkını gösteren Mg-O, Mn-O, Sr-O ve Ba-O bantları da analizler esnasında gözlemlenmiştir.  $SrFe_{12}O_{19}$  için numunenin Sr-Fe içerdiğini gösteren 400-600  $cm^{-1}$  aralığındaki değerler okunmuştur. Aynı analizlerde Sr-O içeriğini gösteren 1400  $cm^{-1}$  civarındaki değerler de görülmüştür.  $BaFe_{12}O_{19}$  ile yapılan analizlerde Ba-Fe bağlarını gösteren 415-500  $cm^{-1}$  aralığındaki değerlerle Ba-O yapılarını gösteren

1625  $\text{cm}^{-1}$  civarındaki deęerler gözlemlenmiştir.  $\text{MgFe}_2\text{O}_4$  ve  $\text{MnFe}_2\text{O}_4$  için yapılan analizlerde de benzer şekilde başarılı sonuçlar elde edilmiş ve Mg-Fe ve Mn-Fe varlığını gösteren 550-600  $\text{cm}^{-1}$  arasındaki deęerlerle sırasıyla Mg-O ve Mn-O varlıklarını işaret eden 1600  $\text{cm}^{-1}$  ve 1650  $\text{cm}^{-1}$  civarındaki deęerler okunmuştur.

FTIR analizlerinde ayrıca oleik asit, silika kaplama ve amünasyon belirtileri de görülmüştür. Oleik asit varlığı içerikteki Fe-COOO, H-C-H ve C-O yapılarından anlaşılmaktadır. Bu bağların varlığını gösteren 1400-1600  $\text{cm}^{-1}$  aralığndaki deęerler, 2920  $\text{cm}^{-1}$  civarındaki deęerler ve 1050  $\text{cm}^{-1}$  civarındaki titreşimler gözlenmiştir. Silika kaplamanın doğruluğunun teyidi Si-O, Si-O-Si ve Fe-O-Si bağlarının varlığının gözlemlenmesiyle yapılmaktadır. Bu bağların varlığı FTIR analizinde Si-O ve Si-O-Si varlığını gösteren 800-1100  $\text{cm}^{-1}$  aralığndaki deęerlerin ve Fe-O-Si varlığını gösteren 580  $\text{cm}^{-1}$  civarındaki deęerlerin okunmasıyla gösterilmiştir. Amünasyonun belirtileri ise O-H ve N-H bağlarının varlığını gösteren 1600  $\text{cm}^{-1}$  ve 3000  $\text{cm}^{-1}$  civarındaki deęerlerin okunmasıyla tespit edilmiştir.

SEM ekipmanıyyla yapılan analizlerle parçacıkların yapıları ve boyutları incelenmiştir. Biyolojik uyumluluk için gerekli olan çap olarak 30 nm'den küçük parçacık boyutları gözlemlenmiştir. Sonuç olarak  $\text{Fe}_3\text{O}_4$  için en büyük boyutun pH deęeri 13 olduğunda ortaya çıktığı görülmüştür, sentezleme esnasında eklenen suyun azaltılması, yani derişikliğin artırılması parçacık boyutunu küçültmektedir. Derişikliğe göre parçacık boyutunun deęişimi doğrusaldır.  $\text{SrFe}_{12}\text{O}_{19}$  için en büyük boyut kullanılan en düşük pH seviyesi olan 12'de elde edilmiştir. Derişim arttıkça parçacık boyutu düşmektedir.  $\text{BaFe}_{12}\text{O}_{19}$  için pH deęeri düşükçe parçacık boyutunun arttığı ve derişim azaldıkça parçacık boyutunun da küçüldüğü görülmüştür.  $\text{MgFe}_2\text{O}_4$  için derişim artışıyla parçacık boyutunun düştüğü görülmüştür. Fakat pH için düzenli bir patern gözlemlenmemiştir.  $\text{MnFe}_2\text{O}_4$  için ise pH ya da derişim ile parçacık boyutu arasında mantıksal bir ilişki kurulamamıştır.

## 1. INTRODUCTION

Cancer is the third leading cause of death(after heart disease and stroke) in developed countries and the second leading cause of death(after heart disease) in the United States. Studies have shown that there were million new cases, 6 million deaths, and 22 million people living with cancer worldwide in the year 2000. These numbers represent an increase of about 22% in incidence and mortality from that of the year 1990. It is projected that the number of new cases of all cancers worldwide will be 12.3 and 15.4 million in the year 2010 and 2020, respectively [1].

Cancers are traditionally treated with surgery, radiation, and chemotherapy. Each of these approaches bears the risk of killing normal cells or fatally damaging healthy tissue. With the emergence and rapid growth of nanotechnology, nanomaterials are providing new opportunities that can assist in the therapeutic index by driving the therapeutic to the target site and limiting its exposure to healthy tissue. Among many nanomaterials studied for cancer diagnosis and therapy, superparamagnetic iron oxide nanoparticles(SPIONs) have emerged as one of the most appealing candidates [2]. Due to rapid advances in nanotechnology, novel synthetic routes to nanoparticles(NPs) with the ability to rigorously control the microstructure of the magnetic core(such as size monodispersity and monodispersity ) have been described. These nanosystems can be made to heat up, which leads to their use as hyperthermia agents, delivering toxic amounts of thermal energy to tumors, or as chemotherapy and radiotherapy enhancement agents where a moderate degree of tissue warming results in more effective cell destruction [3,4]. Numerous forms of MNP with various chemical compositions have been proposed and evaluated for biomedical applications to exploit nanoscale magnetic phenomena, such as enhanced magnetic moments and superparamagnetism. Composition, size, morphology and surface chemistry can now be tailored by various processes to not only improve magnetic properties but also affect the behavior of nanoparticles in vivo. In its simplest form, a biomedical MNP platform is comprised of an inorganic nanoparticle core and a

biomedical MNP and a biocompatible surface coating that provides stabilization under physiological conditions [5].

## **1.1 Purpose of Thesis**

In this research 5 different magnetic nanoparticles including  $Fe_3O_4$ ,  $MgFe_2O_4$ ,  $MnFe_2O_4$ ,  $SrFe_{12}O_{19}$  and  $BaFe_{12}O_{19}$  nanoparticles have been synthesized using precipitation method in room temperature while all the samples have been silica coated using Stöber method. In the next step all MNPs have been aminated for preparing the nanoparticles for gold coating and PEG coating. All five kinds of magnetic nanoparticles have been synthesized in different sizes in the range which they are biocompatible by changing PH and water ratio in the synthesizing process while in every step 3 gram of the samples have been separated for analysis. The samples have been analyzed using FTIR, SEM, VSM in order to study their size changing behavior by changing PH and water ratio in synthesizing condition and studying different magnetic nanoparticles structure and magnetization behavior for further research and biomedical studies.

## **1.2 Literature Review**

### **1.2.1 Magnetism**

#### **1.2.1.1 Nanomagnetism**

The design of MNPs with tailored properties depends of the fundamental concepts of nanomagnetism(i.e., magnetism observed in nanoparticles). A review of what produces magnetization, including the relationship between various extrinsic and intrinsic parameters, will enable us to better evaluate the underlying factors that influence magnetism at the nanoscale. Explanations about the role of atomic and molecular structure upon magnetization are readily available. Based on the response of the intrinsic MNP magnetic dipole and the magnetization in the presence and absence of an applied magnetic field, MNPs are typically classified as:

- Diamagnetics,
- Paramagnetics,
- Ferromagnetic,
- Ferrimagnetic,

- Antiferrimagnetic [6]

Figure 1.1 shows the net magnetic dipole arrangement for each of Diamagnetics, Paramagnetics, Ferromagnetic, Ferrimagnetic and Antiferrimagnetic materials.

### Diamagnetics

For diamagnetic materials in the absence of a magnetic field, magnetic dipoles are not present. However upon application of a field, the material produces a magnetic dipole that is oriented opposite to that of the applied field; thus, a material that has strong diamagnetic character is repelled by a magnetic field.

### Paramagnetics

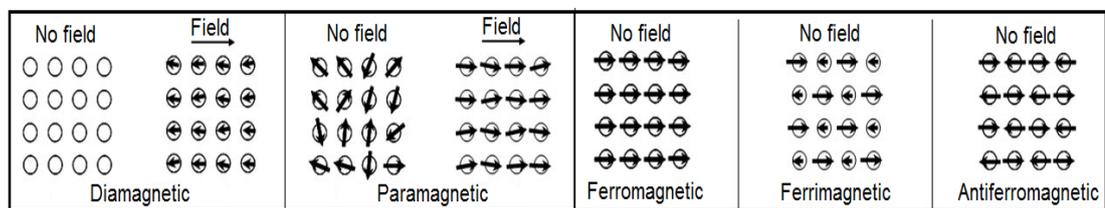

For paramagnetic materials, there exist magnetic dipoles as illustrated in Figure 1.1, but these dipoles are aligned only upon application of an external magnetic field. For the balance of the magnetic properties illustrated in Figure 1.1, the magnetization in the absence of an applied field reveals their fundamental character.

### Ferromagnetic

Ferromagnetic materials have net magnetic dipole moments in the absence of an external magnetic field.

### Ferrimagnetic and antiferrimagnetic

In antiferrimagnetic and ferrimagnetic materials, the atomic level magnetic dipole moments are similar to those of ferromagnetic materials, however, adjacent dipole moments exist that are not oriented in parallel and effectively cancel or reduce, respectively, the impact of neighboring magnetic dipoles within the material in the absence of an applied field.

**Figure 1.1:** Magnetic dipoles and behavior in the presence and absence of an external magnetic field [7].

### 1.2.1.2 Physics of magnetism

When a magnetic material is placed in a magnetic field of strength  $H$ , the individual atomic moments in the material contribute to its overall response; the magnetic moment and induction is given by equations 1.1 and 1.2.

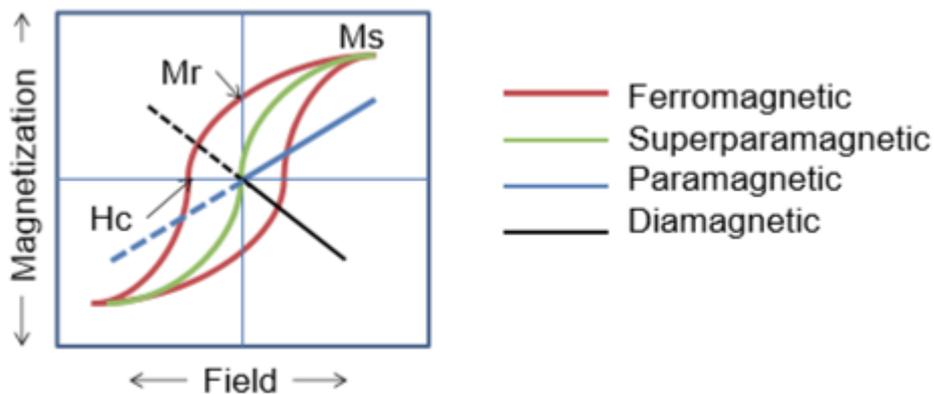

$$M = \chi H \quad (1.1)$$

$$B = \mu_0 (H + M) \quad (1.2)$$

where  $\mu_0$  is the permeability in vacuum and  $M$  is the magnetic moment per volume. The magnetic materials may be conveniently classified in terms of their volumetric magnetic susceptibility,  $\chi$ .

### 1.2.1.3 Hysteresis loop

For MNPs, the maximum magnetization possible is called the saturation magnetization, and it arises when all the magnetic dipoles are aligned in an external magnetic field. Figure 1.2 shows a typical magnetization curve for ferromagnetic or ferrimagnetic nanoparticles showing the characteristic positions on the curve associated with *saturation magnetization* ( $M_s$ , maximum induced magnetization), *remanent magnetization* ( $M_r$ , induced magnetization remaining after an applied field is removed), and *coercivity* ( $H_c$ , the intensity of an external coercive field needed to force the magnetization to zero). In the same figure, in contrast to the hysteresis observed in the case of ferromagnetic nanoparticles (red loop), the response of superparamagnetic nanoparticles to an external field also follows a sigmoidal curve but shows no hysteresis (green line) [7].

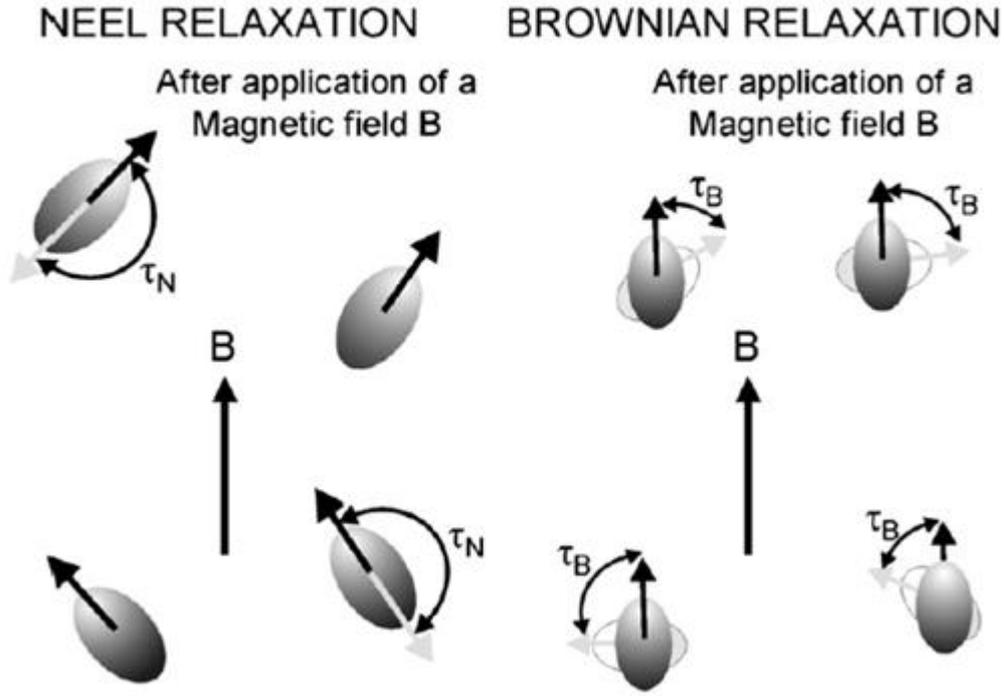

**Figure 1.2:** Hysteresis loop of magnetic nanoparticles [7].

#### **1.2.1.4 Superparamagnetic magnetic nanoparticles**

Research in magnetic nanoparticles typically focuses on developing an optimal response for MNPs to an external magnetic field, and the majority of the published research has involved MNPs that are typically classified as either ferromagnetic, ferrimagnetic, or superparamagnetic particles ( a special case of ferro- or ferrimagnetic particles). Below certain critical dimensions (that vary with the material parameters), MNPs exhibit magnetic responses reminiscent of those of paramagnetic materials, which is a zero average magnetic moment in the absence of an external field and a rapidly increasing (as compared to paramagnetic materials) magnetic moment under application of an external field in the direction of the field. This phenomenon, observed at temperatures above the so-called blocking temperature arises from the thermal fluctuations within nanoparticles being comparable to or greater than the energy barrier for moment reversal, allowing rapid random flipping of the nanoparticle magnetic moments. In the case where the magnetization of the MNP over the measurement/observation interval is equal to zero in the absence of an external field, such nanoparticles are referred to as superparamagnetic. Superparamagnetism is especially important in applications such as drug delivery of MRI, where the nanoparticles exhibit no magnetic properties upon removal of the external field and therefore have no attraction for each other, eliminating the major driving force for aggregation. More importantly, superparamagnetic nanoparticles allow better control over the application of their magnetic properties because they provide a strong response to an external magnetic field [7-9].

#### **1.2.1.5 Heat dissipation mechanism**

In this part, the behaviour and the heating in alternate magnetic field will be presented. Also, the properties of nanoparticles have been shortly discussed. The magnetization of nanoparticles can relax by two different mechanisms, the so-called Neel relaxation and the Brownian relaxation. Neel relaxation is caused by the reorientation of the magnetization vector inside the magnetic core against an energy barrier. Brownian relaxation is due to rotational diffusion of the whole particle in the carrier liquid. Figure 1.3 is illustrating the magnetic nanoparticles orientation and their relaxation status after application of a magnetic field  $B$  their [10,11].

**Figure 1.3:** Illustration of the two components of the magnetic relaxation of a magnetic nanoparticles [3].

Heat dissipation from magnetic particles is caused by the delay in the relaxation of the magnetic moment through either the rotation within the particle (Neel) or the rotation of the particle itself (Brownian), when they are exposed to an AC magnetic field with magnetic field reversal times shorter than the magnetic relaxation times of the particles.

The Neel ( $\tau_N$ ) and Brownian ( $\tau_B$ ) magnetic relaxation times of a particle are given by the following equations:

$$\tau_N = \tau_0 \exp\left(\frac{KV_M}{kT}\right) \quad (1.3)$$

$$\tau_B = \frac{3\eta V_H}{kT} \quad (1.4)$$

$$\tau = \frac{\tau_B \tau_N}{\tau_B + \tau_N} \quad (1.5)$$

where  $\tau_N$  is the Neel relaxation time,  $\tau_B$  the Brown relaxation time  $\tau$  the effective relaxation time,  $\tau_0 = 10^{-9} s$ ,  $K$  the anisotropy constant,  $V_M$  the volume of particle,  $k$

the Boltzmann constant, T the temperature, Z the viscosity and  $V_H$  the hydrodynamic particle volume.

From the above equations, it is clear that the relaxation time relies on the particle diameter. When the particles are exposed to an AC magnetic field with time of magnetic reversals less than the magnetic relaxation times of particles, heat is dissipated due to the delay in the relaxation of the magnetic moment. Thus, the heat dissipation value is calculated using the harmonic average of both relaxations and their relative contributions depending on the particle diameter. The heat dissipation is given by the following equation [11]:

$$P = \mu_0 \chi'' f H_{\text{apply}}^2 \quad (1.6)$$

Where P is the heat dissipation value,  $\mu_0$  the permeability of free space,  $\chi''$  the AC magnetic susceptibility (imaginary part), f the frequency of applied AC magnetic field and  $H_{\text{apply}}$  the strength of applied AC magnetic field.

### 1.2.2 Synthesis methods of magnetic nanoparticles

Magnetic nanoparticles have been synthesized with a number of different compositions and phases, including iron oxides, such as  $Fe_3O_4$  and  $\gamma-Fe_3O_4$ , pure metals, such as Fe and Co, spinel-type ferromagnets such as  $MgFe_2O_4$ ,  $MnFe_2O_4$ ,  $SrFe_{12}O_{19}$  and  $BaFe_{12}O_{19}$ . In the last decades, much research has been devoted to the synthesis of magnetic nanoparticles. Especially during the last few years, many publications have described efficient synthetic routes to shape-controlled, highly stable, and monodisperse magnetic nanoparticles. Several popular methods including co-precipitation, thermal decomposition and/or reduction, micelle synthesis, hydrothermal synthesis, and laser pyrolysis techniques can all be directed at the synthesis of highly-quality magnetic nanoparticles [12].

#### 1.2.2.1 Thermal decomposition

Inspired by the synthesis of high-quality semiconductor nanocrystals and oxides in nan-aqueous media by thermal decomposition, similar methods for the synthesis of magnetic particles with control over size and shape have been developed. Monodisperse magnetic nanocrystals with smaller size can essentially be synthesized

through the thermal decomposition of organometallic compounds in high-boiling organic solvents containing stabilizing surfactants. The rapid injection of the reagents, often organometallic compounds, into hot surfactant solution gas yielded with respect to coprecipitation methods markedly improved samples with good size control, narrow size distribution and good crystallinity of individual and dispersible Fe-based magnetic nanoparticles [4,6,13-15].

#### **1.2.2.2 Microemulsion**

A microemulsion can be defined as a thermodynamically stable isotropic dispersion of two immiscible liquids consisting of nanosized domains of one liquid in the other, stabilized by an interfacial film of surface-active molecules. The surfactant molecules provide a confinement effect that limits particle nucleation, growth and agglomeration. In this method, coprecipitation occurs in tiny droplets of water ("water pools") embedded with surfactant molecules and homogeneously distributed in an oil phase. [13,16-18,19].

#### **1.2.2.3 Hydrothermal synthesis**

Hydrothermal technique is defined as any heterogeneous reaction in the presence of aqueous solvents or mineralizers under high pressure and temperature conditions. Hydrothermal treatment of iron salt could generate iron oxides when the applied conditions are appropriate [16]. Under hydrothermal conditions a broad range of nanostructured materials can be formed [13].

#### **1.2.2.4 Laser pyrolysis**

The laser pyrolysis method involves heating a flowing mixture of gases with a continuous wave carbon dioxide laser, which initiates and sustains a chemical reaction. Above a certain pressure and laser power, a critical concentration of nuclei is reached in the reaction zone, which leads to homogeneous nucleation of particles that are further transported to a filter by an inert gas. Three characteristics for this method must be emphasized: (a) the small particle size, (b) the narrow particle size distribution, and (c) the nearly absence of aggregation [14].

### 1.2.2.5 Reverse Micelle method

Reverse Micelles have been used to synthesize a wide variety of nanoparticles including metallic, bimetallic, metal oxide and semiconducting particles. The general process consists of formulating a water in oil microemulsion from a ternary water/oil/surfactant system. Next, the desired reaction precursor(s), such as a water soluble metal salt for metallic nanoparticles, are dissolved into the aqueous centers of the micelle. A reducing agent, is then added, either by simple injection, or dispersed in analogous reverse micelles and added to the system. When the salt is reduced by the reducing agent, active metal nuclei are formed. The nuclei-containing micelles then collide under Brownian motion and may exchange their contents causing the metal particles to grow. The greater the average number of successful collisions, the larger the particles [20].

### 1.2.2.6 Co-precipitation

Co-precipitation is a facile and convenient way to synthesize  $MFe_nO_m$  (M: Fe, Sr, Ba, Mn, Mg.  $n=2,12$  and  $m=4,19$ ) magnetic nanoparticles from aqueous  $Fe^{2+}/Fe^{3+}$  salt solution by the addition of a base under inert atmosphere at room temperature or at an elevated temperature. The size, shape, and composition of the type of salts used (e.g. chlorides, sulfates, nitrates), the  $Fe^{2+}/Fe^{3+}$  ratio, the reaction temperature, the pH value and ionic strength and the concentration of materials in synthesis environment [21-25]. Among the various synthesis procedures of the magnetic nanoparticles ( $MFe_xO_y$ ), most commonly used solution phase procedure has been the co-precipitation of  $Fe^{2+}$  and  $Fe^{3+}$  ions and different M materials including (Sr, Ba, Mn and Mg) ions by an alkali, usually  $NH_4OH$  or  $NaOH$  in an aqueous solution. Although this method is most suitable and convenient for mass production of magnetic nanoparticles based ferrofluids with desired properties, it requires careful maintenance of  $Fe^{2+}:Fe^{3+}$  ions and M ions ratio and the adjustment for pH value of the solution for the formation of magnetic nanoparticles. In literature there are plenty of studies in synthesizing magnetic nanoparticle core by co-precipitation method for biomedical purposes. Synthesizing magnetite nanoparticles for biomedical applications and hyperthermia has been attracted most of the attentions and since nearly most of the synthesizing magnetic nanoparticles include  $Fe_3O_4$  for its good

behavior in the biomedical applications [21,25-31]. About synthesizing  $SrFe_{12}O_{19}$ ,  $BaFe_{12}O_{19}$ ,  $MgFe_2O_4$  and  $MnFe_2O_4$  magnetic nanoparticles there are few research and experiments by co-precipitation method [32-40]. We see that in all research and experiments authors have changed magnetic nanoparticles size and structure by changing different parameters like PH, material molar ratio, temperature, stirring speed and material concentration in used DI water, used in co-precipitation method. In this project by studying different papers and their results and parameters that have been varied for synthesizing nanoparticles and according some reference and their particle sizes [28, 41-44]. Table 1.1 is a summary of synthesizing magnetic nanoparticles in different sizes which different parameters like pH, stirring speed, temperature or used catalyst are different and as a results nanoparticles size is different from each other under different conditions. Figure 1.4 shows nanoparticles sizes by changing the pH of the reaction system. Figure 1.5 depicts the nanoparticle sizes in different reaction temperature. Figure 1.6 is shows nanoparticles size variation in different stirring rates and Figure 1.7 shows XRD results for  $Fe_3O_4$  in different sizes and Figure 1.8 represents magnetization change of magnetic nanoparticles in different diameter sizes. We decided to have 5 different type of nanoparticles( $SrFe_{12}O_{19}$ ,  $BaFe_{12}O_{19}$ ,  $Fe_3O_4$ ,  $MgFe_2O_4$  and  $MnFe_2O_4$ ) by changing the PH and concentration of nanoparticles in the DI water environment while our synthesizing condition and results will be explained in Table 1.1.

**Table 1.1:** Parameters for synthesizing  $Fe_3O_4$  nanoparticles in different sizes using co-precipitation method available in literature.

### 1.2.3 Surface functionalization of magnetic nanoparticles

Surface modification of magnetic nanoparticles is often necessary in order to achieve ferrofluidic stability, solubility in a certain solvent environment or in order to introduce molecular entities on the surface serving either as sites for further functionalization or as molecular probes in biotechnological applications. Immobilization of biomolecules onto the surface of magnetic nanoparticles is a process commonly denoted bioarticles functionalization. There exist numerous publications on biofunctionalization of magnetic nanoparticles in the scientific literature and by that also a large number of coupling chemistries [45]. In general surface modification for cancer therapy application includes oleic acid coating [46,47] for preventing oxidation of magnetite nanoparticles and silica coating[48-62] for preventing agglomeration and amination[63-68] for preparing them for gold coating [63-67,69-76] for making them intoxic for body organs and polymer coating [68,77-86] for making them biocompatible for attaching to body organs and cells. Figure 1.9 is represents magnetic nanoparticles core synthesis and in the following its surface coatings which includes silica coating, amination and gold decoration and changing it to gold shell coating.

**Figure 1.9:** (a) Magnetic nanoparticle core (b) Silica coated (c) Aminated (d) Gold decoration (e) Gold shell coating [67].

## 2. MATERIALS AND EQUIPMENTS

The following chapter presents chemical reagents and devices used for the nanoparticle synthesis, the nanoparticle characterization and the heating experiments.

### 2.1 Chemical Reagents

Hereafter all used reagents are summed up with details of their chemical formula, purity, company and country of manufacture and possible abbreviations in **Error! eference source not found.** 1. All chemical were used without further purification or treatment.

**Table 2.1:** Materials used for synthesizing nanoparticle cores, silica coating and amination.

Trade name	Chemical formula	Purity [%]	Company / Country of Manufacture
Magnetic core fabrication of Fe <sub>3</sub> O <sub>4</sub> - and SrFe <sub>12</sub> O <sub>19</sub> -nanoparticles			
Iron (II) chloride tetrahydrate	FeCl <sub>2</sub> · 4H <sub>2</sub> O	99	Merck, Germany
Iron (III) chloride hexahydrate	FeCl <sub>3</sub> ·6H <sub>2</sub> O	99	Merck, Germany
Strontium (II) nitrate (dry)	Sr(NO <sub>3</sub> ) <sub>2</sub>	99	Kimetsan, Turkey
Barium nitrate (dry)	Ba(NO <sub>3</sub> ) <sub>2</sub>	0	Merck, Germany
Magnesium nitratehexahydrate(dry)	Mg(NO <sub>3</sub> ) <sub>2</sub> ·6H <sub>2</sub> O	-	Merck, Germany
Manganese (II) nitrate (dry)	Mn(NO <sub>3</sub> ) <sub>2</sub> ·4H <sub>2</sub> O	-	Merck, Germany

**Table 2.1 (continued):** Materials used for synthesizing nanoparticle cores, silica coating and amination.

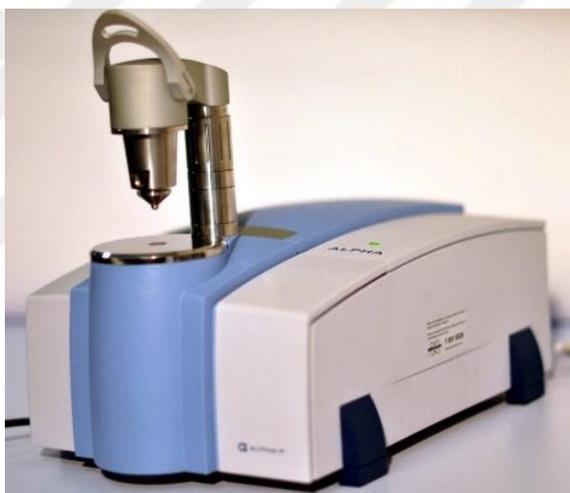

Trade name	Chemical formula	Purity [%]	Company / Country of Manufacture
Manganese (II) nitrate (dry)	$\text{Mn}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$	-	Merck, Germany
Sodium hydroxide	NaOH	97	Merck, Germany
Oleic acid	$\text{C}_{18}\text{H}_{34}\text{O}_2$	98	ZAG, Turkey
N-hexane	$\text{C}_6\text{H}_{14}$	95	Merck, Germany
De-ionized water	De-ionized water generated via evaporation. Evaporator was purchased from Nüve.		
Silica coating and amination			
Tetraethyl orthosilicate	$\text{C}_8\text{H}_{20}\text{O}_4\text{Si}$	98	Sigma-Aldrich, Germany
3-Aminopropyltrimethoxy-silane	$\text{H}_2\text{N}(\text{CH}_2)_3\text{Si}(\text{OCH}_3)_3$	-	Flurochem, U.K.
Ammonia solution	$\text{NH}_4\text{OH}$	25 wt. %	Merck, Germany
2-propanol	$\text{C}_3\text{H}_8\text{O}$	99,5	Merck, Germany

## 2.2 Devices for Nanoparticle Characterization

In the following the function and specification of used devices for the nanoparticle characterization (FTIR, VSM, SEM and vacuum pump) are discussed.

### 2.2.1 Bruker optics ALPHA-Transmittance FTIR spectrometer

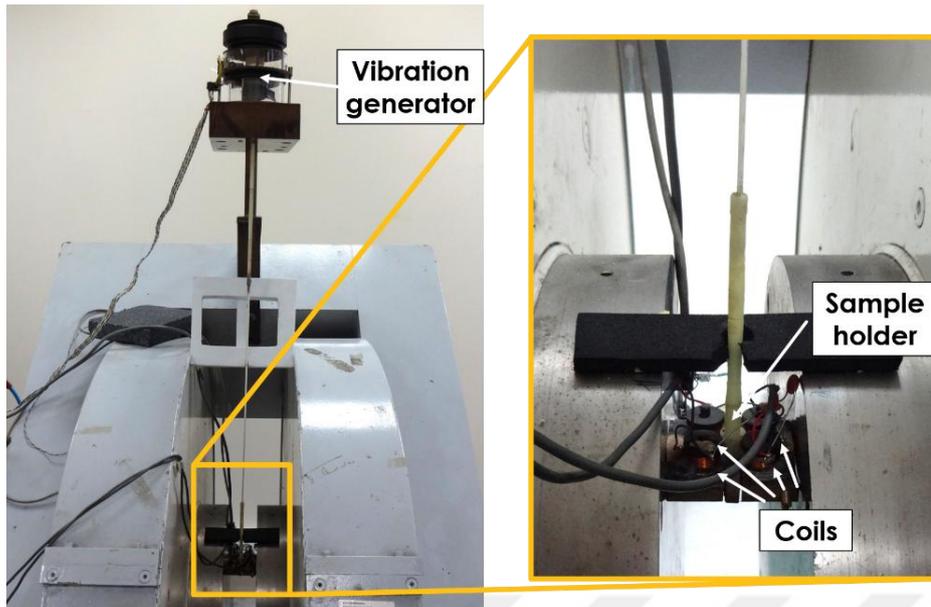

The principle of Fourier transform infrared spectroscopy bases on the specific absorption of electromagnetic waves of chemical groups like alcohol, amine or carboxyl groups. It is commonly used to verify successful surface modifications. Figure 2.1 is our used Bruker optics ALPHA-Transmittance FTIR spectrometer in laboratory which we have measured our samples FTIR using this instrument.

**Figure 2.1:** Bruker optics ALPHA-Transmittance FTIR spectrometer.

### 2.2.2 Vibrating sample magnetometer (VSM)

The VSM measurements were performed at the Physics Department of Istanbul Technical University. A homemade device was utilized, which is visualized in Figure 2.2 where our samples cansules are being positioned inside the sample holder one by one .

**Figure 2.2:** Vibrating sample magnetometer (VSM).

Figure 2.3 shows the pump which we used for making the vacuum situations inside the white dish where we put our samples after drying in the water bath inside it and the pump is sucking the last probable water remaining in the samples by making a vacuum situation inside the dish.

**Figure 2.3:** Vacuum pump a) stand alone b) connected to the drying space.

### 3. METHODS

In our work we used co-precipitation method in order to synthesize magnetic nanoparticle cores.  $Fe_3O_4$  magnetic nanoparticles were oleic acid coated in order to prevent oxidation. In the next step all of the magnetic nanoparticles were silica coated using Stöber method in order to prevent nanoparticles agglomeration and make them biocompatible. In the final step of our work particles were aminated making magnetic nanoparticles ready for gold coating and PEG coating for future works.

The mentioned surface coatings make magnetic nanoparticles ready to enter into human organs for biomedical applications like hyperthermia which is our main goal.

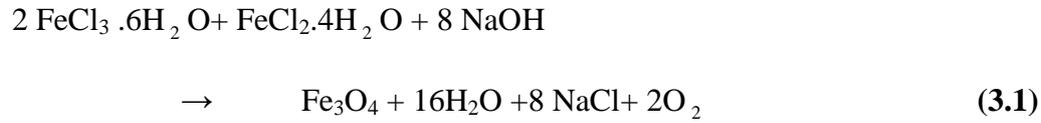

#### 3.1 Core Synthesizing

In this project we synthesised 5 different magnetic nanoparticles including  $Fe_3O_4$ ,  $MgFe_2O_4$ ,  $MnFe_2O_4$ ,  $SrFe_{12}O_{19}$  and  $BaFe_{12}O_{19}$  in different sizes by precipitation method and changing the PH of the solution via changing the amount of the alkaline (NaOH) and changing the concentration of synthesizing solution by changing the amount of the used DI water for synthesizing 20gr of each sample. Table

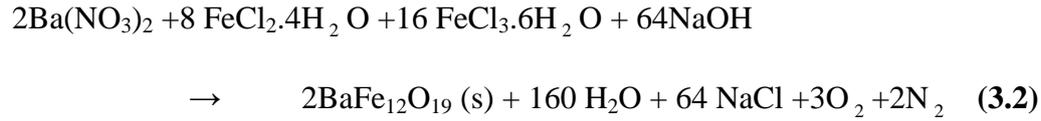

In our work we used the formulation of the reaction for choosing the amount of the materials for synthesizing each kind of the nanoparticle. Equations 3.1-3.5. In this method  $Fe_3Cl_6.OH$ ,  $Fe_2Cl_4.OH$  and half of the used water in hole process was mixed together under 300rpm for 30minutes (Figure 3.1) and then NaOH solved in the other half of the DI water and simultaneously with  $Sr(NO_3)_2$  or  $Ba(NO_3)_2$  or  $Mg(NO_3)_2.6H_2O$  or  $Mn(NO_3)_2.4H_2O$  was added to the solution depending on the required kind of nanoparticle and was stirred for another 3 hours (Figure 3.2). And then decanted using magnets, measuring the PH of the solution and then washing till their 7 PH (Figure 3.3).

During Precipitation for synthesizing nanoparticles these chemical reactions are occurring:

## 3.2 Magnetic Nanoparticles Surface Coating

### 3.2.1 Oleic acid coating

In this project before starting to synthesizing nanoparticles in large amount nanoparticles were synthesized in little amount of 3gr to study their behavior and as in the first step synthesized one sample as a core from each magnetic nanoparticles we noticed just  $Fe_3O_4$  oxidized after synthesis and  $SrFe_{12}O_{19}$ ,  $BaFe_{12}O_{19}$ ,  $MgFe_2O_4$  and  $MnFe_2O_4$  are stable and don't be oxidized. So in order to stop  $Fe_3O_4$  magnetic nanoparticles from oxidation they became oleic acid coating that oleic acid was mixed to the solution after 2 hours when NaOH and the third material was added to  $Fe^{3+}$  and  $Fe^{2+}$  mixture and after testing different amount of oleic-acid we decided to add 0.1 ml of oleic-acid for synthesizing 1gr of nanoparticles.

### 3.2.2 Silica coating and amination of the magnetic nanoparticles

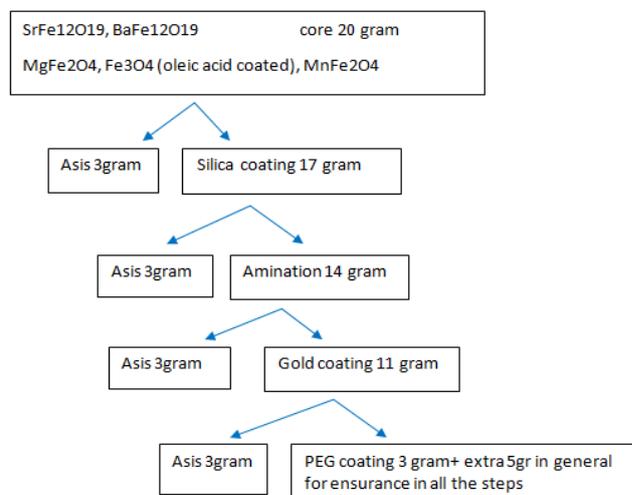

In the third step nanoparticles were silica coated using Stober method. After going through the available literatures in this field as I mentioned before we chose several literatures and as the amount of the TEOS and Ammonia and kind of Alcohol effects the silica coating thickness and its structure and particles agglomeration we used references in choosing the amount of TEOS and kind of alcohol (ethanol 25%) and amount of the ammonia as have been represented in Table 3.6. First water, nanoparticles and ethanol were mixed together under 300rpm for 30 minutes and after that Ammonia and TEOS were added to the solution and were stirred for another 3 hours then calculated amount of the solution containing 3gr of nanoparticles were separated as silica coated nanoparticles and were decanted and washed for 5

times. The other remained nanoparticles were aminated as after adding APTES the solution were stirred under 300rpm for another 6hours and then were decanted and washed 5 times.

**Table 3.6:** Used silica coating references and our methods.

Method	Thickness (nm)	NP core (nm)	TEOS	Solvent	Water (ml)	Amonia (ml)	Temperature
E. Ghasemi 2012	8	11	0.75 g	0.75 ml EtOH	5	0.75	40°C
Michael 2014	2	-	1.43 ml	286 ml (2-ProOH <sub>2</sub> )	60	8.58	Room Temp.
M.Kuzminskaa 2015	2	-	0.15 ml	284.7 ml (IsoproOH)	56.9	10.67	Room Temp.
YH Deng 2005	-	-	0.5 ml	80 EtOH	20	1.5	Room Temp.
Values in this project	-	-	0.5 ml	284.7ml EtOH	56.9	10.67	Room Temp.
New values in this project (successful)	4-6	-	0.5 ml	133ml EtOH	33	10.67	Room Temp.
Other values in this project (unsuccessful)	-	-	0.5 ml	133 ml EtOH	33	4	Room Temp.

Figure 3.4 shows general plan for our magnetic synthesis and their future surface coatings. Figure 3.5 to 3.8 are the images of prepared samples which in every bottle there is 3 gram of magnetic nanoparticles core, 3gram silica coated and 3 gram of aminated for each of 44 core samples which in total there are 132 samples.

**Figure 3.4:** Our general plan in synthesizing.

**Figure 3.5:** Prepared nanoparticles.

**Figure 3.6:** Prepared cores of the nanoparticles

**Figure 3.7:** Silica coated nanoparticles

**Figure 3.8:** Aminated nanoparticles.

### **3.2.3 Nanoparticle powder preparation for FTIR and VSM measurements**

We dried 1 gram of each sample about 30 ml of nanoparticle solution in the water bath under  $70-90^{\circ}C$  temperature for about 10 hours in the 50ml baker (Figure 3.9) and then we put samples in the ambient place for evaporating the remained water and

then milled with a mortar (Figure 3.11). Our final powder magnetic nanoparticles have been shown in Figure 3.12 and Figure 3.13.

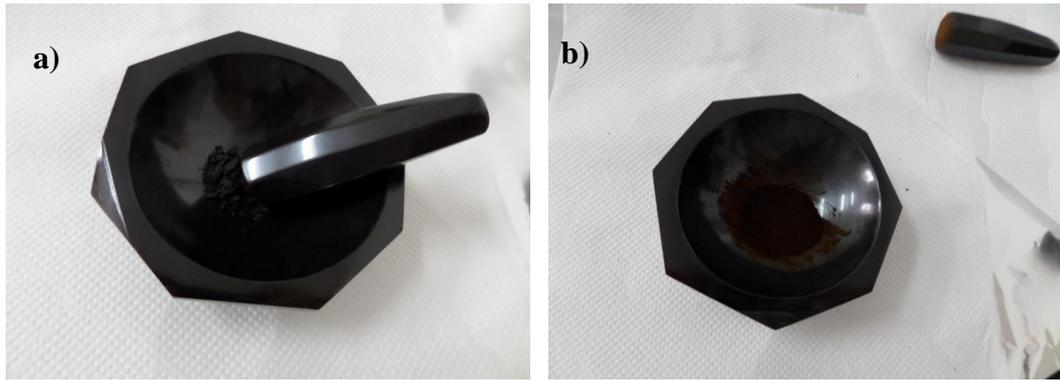

**Figure 3.9:** Drying magnetic nanoparticles in water bath in 80°C.

**Figure 3.10:** Putting samples in the vacuum space for the final complete drying.

**Figure 3.11:** Equipments used magnetic nanoparticle powder making.

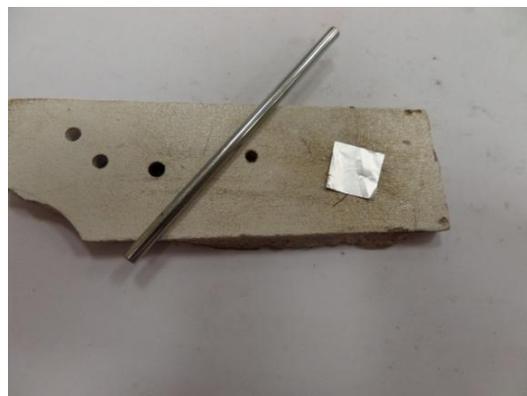

**Figure 3.12:** Dried Nanoparticles a) in dicer b) after making powder.

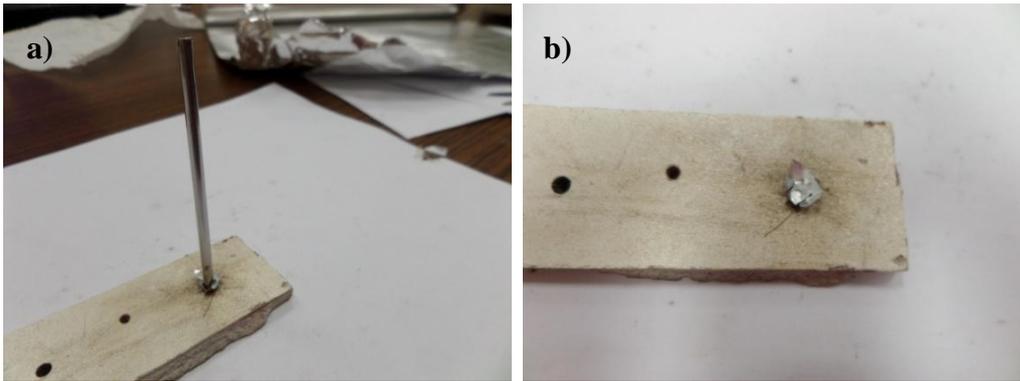

**Figure 3.13:** Final prepared samples.

#### **3.2.4 Making capsules out of nanoparticles for VSM**

Magnetic Nanoparticles of each samples were prepared for VSM measurements by making capsules which the weight of the embedded nanoparticles in each capsule made of foil should be more than 20 mg. Figure 3.14. Figure 3.15 is the process we have made capsules out of foil and after weighing them and calibrating Figure 3.16 capsules have been filled with nanoparticle powders Figure 3.17.

**Figure 3.14:** Instruments used for making capsules.

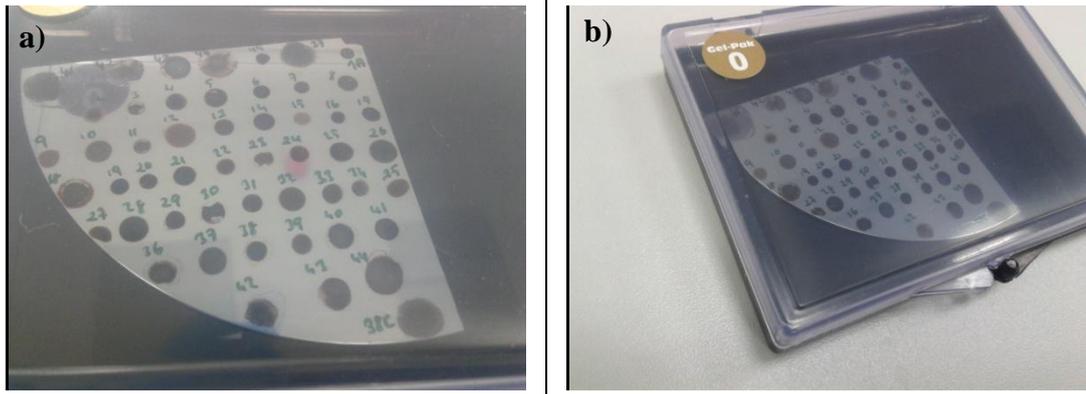

**Figure 3.16:** Calibrating the weighing device regarding the empty container foil a) weight of the foil b) close view.

**Figure 3.17:** a) Filling nanoparticle powder into the capsule b) closing the capsule c) final sample.

### 3.2.5 Sample preparation for SEM measurements

For measuring the magnetic core size and observing samples structure droplets of Magnetic nanoparticles solution were dried on silicon wafer as we can see in Figure 3.18.

**Figure 3.18:** Dried droplets of nanoparticles core solution a) close view b) box view.

#### 4. RESULTS AND DISCUSSION

In our synthesizing magnetic nanoparticles in different pH and concentrations some of the samples with low concentrations which have been achieved by reducing the DI used water (1000 ml DI water for synthesizing 20 gram magnetic nanoparticles) were not successful so the water amount have been change to 1200 ml water in order to synthesize magnetic nanoparticles in high concentration. In addition as reducing the amount of NaOH for low pH there is a limitation for amount of pH. In another word, when amount of NaOH was reduced in order to reach to 8 or 9 complete precipitation did not occur and all the materials could not participate in precipitation reaction and in these situations which have been called **Failed** (Negative sign in success column) in Table 3.2, Table 3.3 and Table 3.5 solution pH reached to 4-5. Generally speaking reaction pH for  $\text{Fe}_3\text{O}_4$  were 13, 12.5, 10.5 and 5.5 and for  $\text{SrFe}_{12}\text{O}_{19}$  were 14, 13 and 12, for  $\text{BaFe}_{12}\text{O}_{19}$  were 14, 13, 12 and 11, for  $\text{MgFe}_2\text{O}_4$  were 13, 12, 6 and for  $\text{MnFe}_2\text{O}_4$  were 13,12 and 6.

Tables A.1 to A.5 are representing the magnetic nanoparticles and silica coated magnetic nanoparticles and aminated magnetic nanoparticles codes; given for each of them in order to clarify the results and for better understanding. And after representing the related codes FTIR results have been presented in Figures A.1 to A.44 and in the following SEM results for magnetic nanoparticles core and their dimension have been presented and at the end VSM results have been included results have been discussed.

As we have different nanoparticles ( $\text{Fe}_3\text{O}_4$ ,  $\text{SrFe}_{12}\text{O}_{19}$ ,  $\text{BaFe}_{12}\text{O}_{19}$ ,  $\text{MgFe}_2\text{O}_4$  and  $\text{MnFe}_2\text{O}_4$ ) in different synthesizing conditions all of the samples in FTIR have been analyzed in order to study their structure and to make sure that nanoparticles have been coated by Tetraethyl orthosilicate and (3-Aminopropyl)triethoxysilane. As we have summarized in Table 4.1 every material has a specific vibration peak like a finger print and by using FTIR we can identify the structure of materials. In our magnetic nanoparticles as they are referred as ferrofluids Fe vibration bands (Fe-O, and Fe-O-Fe) are in the range between  $500\text{-}650\text{cm}^{-1}$  [87-91]. As we can see the

numbers between 540-570 in all of our samples demonstrating the presence of Fe-O and Fe-O-Fe bands in our magnetic nanoparticles. In addition we represent vibration of another bands in our samples showing the Mg-O, Mn-O , Sr-O, Ba-O, Sr-Fe, Ba-Fe, Mg-Fe and Mn-Fe representing the differences between magnetic nanoparticles as in the SrFe<sub>12</sub>O<sub>19</sub> nanoparticles vibration bands between 400-600 cm<sup>-1</sup> [92,93,94] represent the Sr-Fe and around 1400 cm<sup>-1</sup> represent Sr-O bands in the materials. And weak bands in 662, 586,554 and 440 cm<sup>-1</sup> [2] can be seen in Stransiom Fereit nanoparticles. Vibration bands of Ba-Fe in BaFe<sub>12</sub>O<sub>19</sub> nanoparticles are in the range of 415-500 cm<sup>-1</sup> [95,96] and Mg-Fe vibration bands are expected between 580 cm<sup>-1</sup> and 600 cm<sup>-1</sup> and Mg-O vibration bands are around 1600 cm<sup>-1</sup> [97,98,99]. Furthermore, Mn-Fe and Mn-O vibration bands can be seen in 550 and 1650 cm<sup>-1</sup> [100,101]. And oleic acid coating, silica coating and amination of magnetic nanoparticles FTIR analysis represent a vibration arond 950-1700 as their details have been shown in table 4.1 referring to previous researches. And as our samples number are not small and we have 5 kind of magnetic nanoparticles as mentioned previously we tried to summarize our FTIR results in table 4.2.

In the SEM equipment we observed the structure of particles and measured their sizes which all were less than 30 nm in diameter as we were accepted for their biocompatibility purpose and in our samples we observed that in synthesizing Fe<sub>3</sub>O<sub>4</sub> nanoparticles as PH 13 is the the largest, largest diameters have been achieved and as the amount of synthesig added water decreases mean, the concentration increases the nanoparticles size decreases and their behavior is linear . SrFe<sub>12</sub>O<sub>19</sub>nanoparticles largest sizes can be seen in the lowest PH condition which was 12 and as concentration increases their size is decreasing. In BaFe<sub>12</sub>O<sub>19</sub> nanoparticles as decreases nanoparticle size increases and as concentration increases their size increases. In MgFe<sub>2</sub>O<sub>4</sub> as concentration increases particles size decreases but there is no regular pattern between PH and particle size in our samples. And in MnFe<sub>2</sub>O<sub>4</sub> nanoparticles no logical relation between PH and concentration and nanoparticle size have been seen. Generally speaking, except in Barium Fereit, in Figure B.6 as concentration decreases nanoparticles diameter size increases which it is visversa in Barium Ferreit and as reaction concentration decreases particle size decreases. And as maximum nanoparticle diameter size have been achieved in largest PH in Fe<sub>3</sub>O<sub>4</sub> and SrFe<sub>12</sub>O<sub>19</sub> nanoparticles synthesis reactions and maximum nanoparticle size for bBaFe<sub>12</sub>O<sub>19</sub> and MgFe<sub>2</sub>O<sub>4</sub> has been achieved in smallest reaction pH. But in order to our results we can not speake for sure that the minimum nanoparticles size have been in smallest or largest pH. From structure view seen in the SAM images, magnetic nanoparticles in concentration that 1200 ml water have been used do not have good structures and it seems that some other reactions have happened and some of materials have could not participate in reaction. And the nanoparticles which 2000

and 3000 ml DI water have been used for synthesizing 20 gram of each magnetic nanoparticles have much better structure and we can see a clear image of nanoparticles in the SAM results.

The magnetic properties were measured at room temperature (Figures C.1 to C.45) As we can see, the magnetization curve is to be without hysteresis, the coercivity field and remnant magnetization cannot be found from the curve. It confirms that magnetic nanoparticles are characteristic of superparamagnetic properties. From the magnetization curve, we can also see that the saturation magnetization ( $M_s$ ) of all the magnetic nanoparticles increase when the sizes of magnetite increase, which can be attributed to the increase of weight and volume of magnetite nanoparticles. Also as it was expected that with silica coating and amination magnetic properties decrease it is evident that in some samples due to magnetic nanoparticles surface coated and increase in their weight their saturation magnetization have increased.

From the  $Fe_3O_4$  magnetic nanoparticles magnetization curve Figure C.1 to Figure C.9, it is apparent that aminated nanoparticles saturation magnetizations is higher than silica coated and cores which have been Oleic-acid coated for preventing oxidation. Explanation for this experiment results most probably is that during amination of silica coated and oleic acid coated of  $Fe_3O_4$  magnetic nanoparticles previous coated layers have been removed from surface of magnetic nanoparticles and in FTIR results in silica coated and aminated oleic acid bonds are so weak or there is no band related to oleic-acid bands in aminated nanoparticles. In addition some of aminated  $MgFe_2O_4$  and  $MnFe_2O_4$  nanoparticles have higher saturation magnetization than silica coated ones which is again can be explained by removal of silica coated layer during amination. Furthermore, increase of the weight and volume of magnetic nanoparticles after amination can effect the saturation magnetization of nanoparticles.

From the results we see that nanoparticles with larger size have higher saturation magnetization but since there is a big range of nanoparticle size with different size in different pH and concentration it seems difficult to conclude about nanoparticles size and magnetization power and as all 5 kind of magnetic nanoparticles with 12 nm size magnetization have been compared in Figure C.45. It is evident that Strantium Fereit has the highest Magnetization power under the applied field and Manganese Fereit is

the second nanoparticles in magnetization power and the third powerful magnetic nanoparticle is Magnetite stronger than Barium Fereit and the last kind of nanoparticles in magnetization power are Mangesium Fereit.

## 5. FUTURE WORK

As in this project different magnetic nanoparticles and their FTIR analyses for each sample and silica coated and aminated nanoparticles have been produced and nanoparticles size and their structure have been analyzed in future works researchers can use the optimized samples in size and structure to continue their studies and these results can be a good resource for the future researchers who are working on synthesizing  $\text{Fe}_3\text{O}_4$ ,  $\text{SrFe}_{12}\text{O}_{19}$ ,  $\text{BaFe}_{12}\text{O}_{19}$ ,  $\text{MgFe}_2\text{O}_4$  and  $\text{MnFe}_2\text{O}_4$  magnetic nanoparticles. In addition all of the magnetic synthesized magnetic nanoparticles have been silica coated and aminated for preparing these nanoparticles for gold coating and PEG coating in order to be biocompatible for their application in cancer therapy and as there is a limit for magnetic nanoparticles between 30-60 nm nanoparticles for successful magnetic nanoparticles hyperthermia. These nanoparticles sizes and structure analysis in FTIR and SAM can be a ready resource for future coating and studies. Furthermore VSM results measured for any of magnetic nanoparticles in different sizes can open a new window for their magnetization intensity under magnetic field and their heating performance.

APPENDIX C: VSEM Results

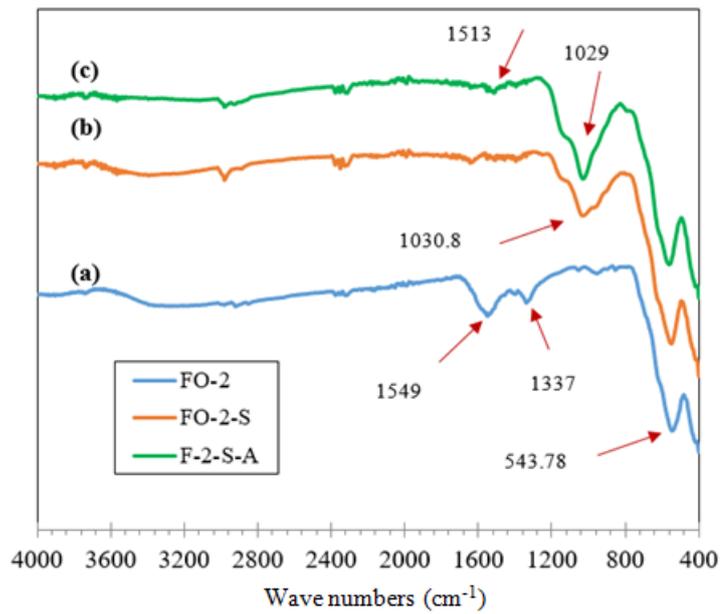

## APPENDIX A

**Table A.1:** Fe<sub>3</sub>O<sub>4</sub> magnetic nanoparticles and silica coated and aminated magnetic nanoparticles given codes.

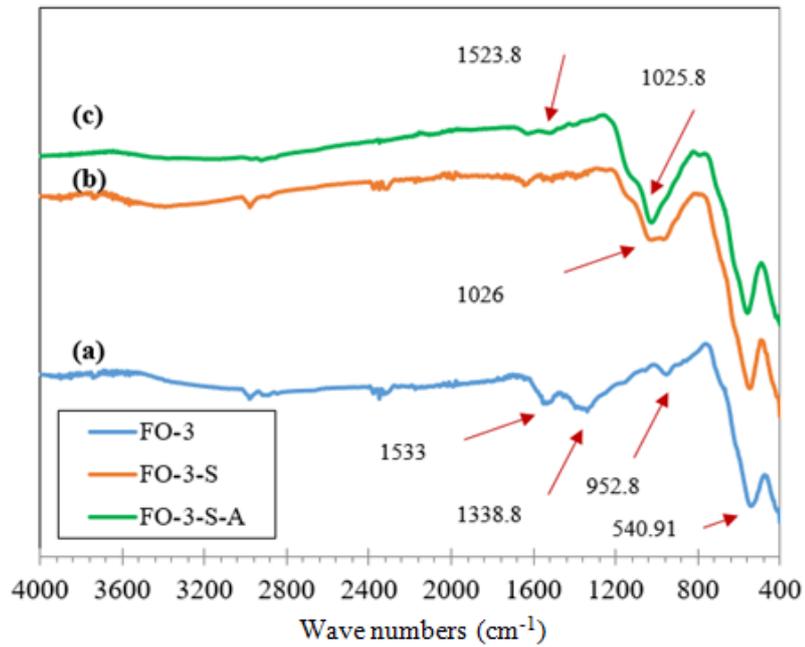

Material	Condition	Code
	Core	FO-1
Fe <sub>3</sub> O <sub>4</sub>	Silica coated	FO-1-S
	Aminated	FO-1-S-A
	Core	FO-2
Fe <sub>3</sub> O <sub>4</sub>	Silica coated	FO-2-S
	Aminated	FO-2-S-A
	Core	FO-3
Fe <sub>3</sub> O <sub>4</sub>	Silica coated	FO-3-S
	Aminated	FO-3-S-A
	Core	FO-4
Fe <sub>3</sub> O <sub>4</sub>	Silica coated	FO-4-S
	Aminated	FO-4-S-A
	Core	FO-5
Fe <sub>3</sub> O <sub>4</sub>	Silica coated	FO-5-S
	Aminated	FO-5-S-A
	Core	FO-6
Fe <sub>3</sub> O <sub>4</sub>	Silica coated	FO-6-S
	Aminated	FO-6-S-A
	Core	FO-7
Fe <sub>3</sub> O <sub>4</sub>	Silica coated	FO-7-S
	Aminated	FO-7-S-A
	Core	FO-8
Fe <sub>3</sub> O <sub>4</sub>	Silica coated	FO-8-S
	Aminated	FO-8-S-A
	Core	FO-9
Fe <sub>3</sub> O <sub>4</sub>	Silica coated	FO-9-S
	Aminated	FO-9-S-A

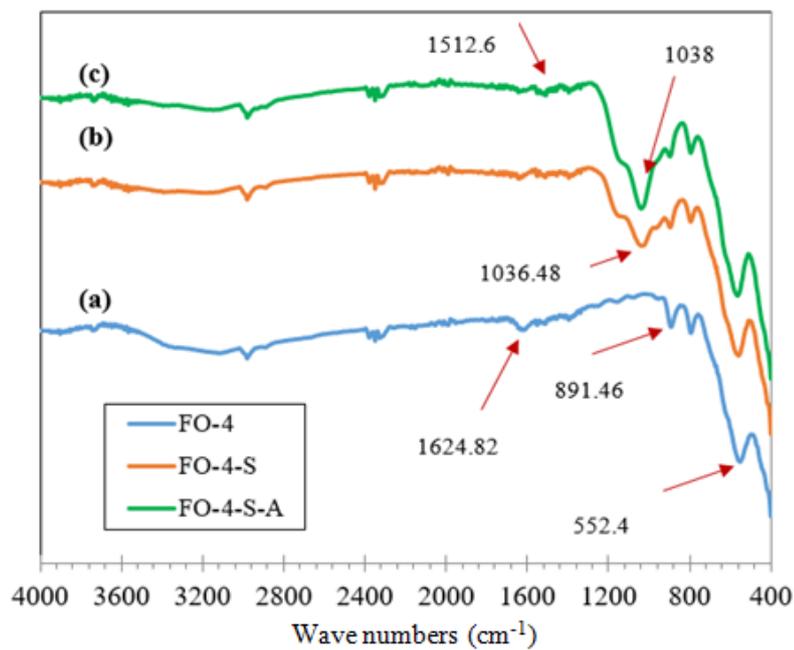

**Figure A.1:** FTIR analysis results of FO-1 samples (a) core, (b) silica coated, (c) aminated.

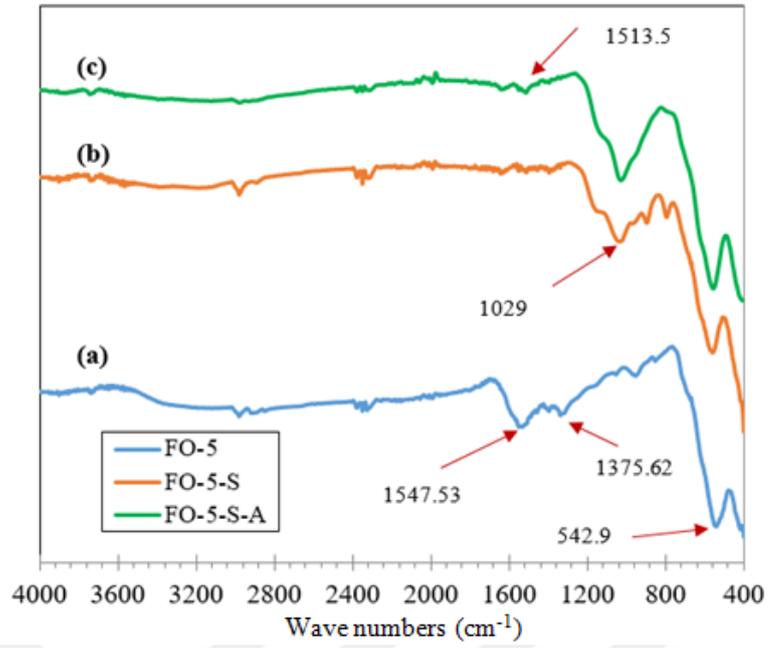

**Figure A.2:** FTIR analysis results of FO-2 samples (a) core, (b) silica coated, (c) aminated.

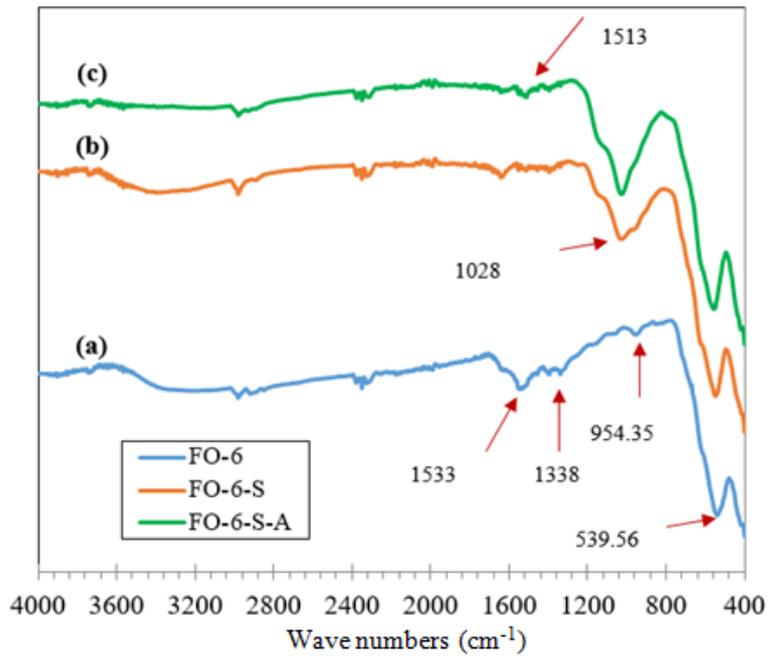

**Figure A.3:** FTIR analysis results of FO-3 samples (a) core, (b) silica coated, (c) aminated.

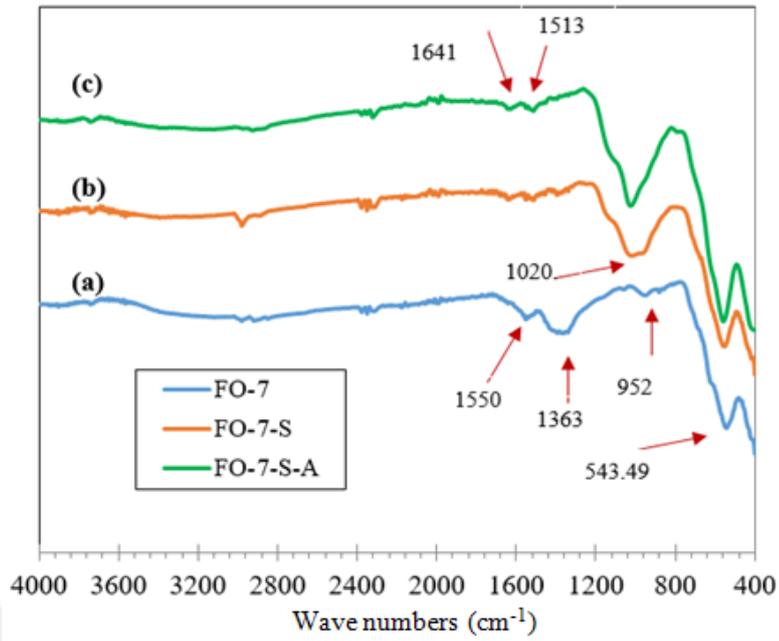

**Figure A.4:** FTIR analysis results of FO-4 samples (a) core, (b) silica coated, (c) aminated.

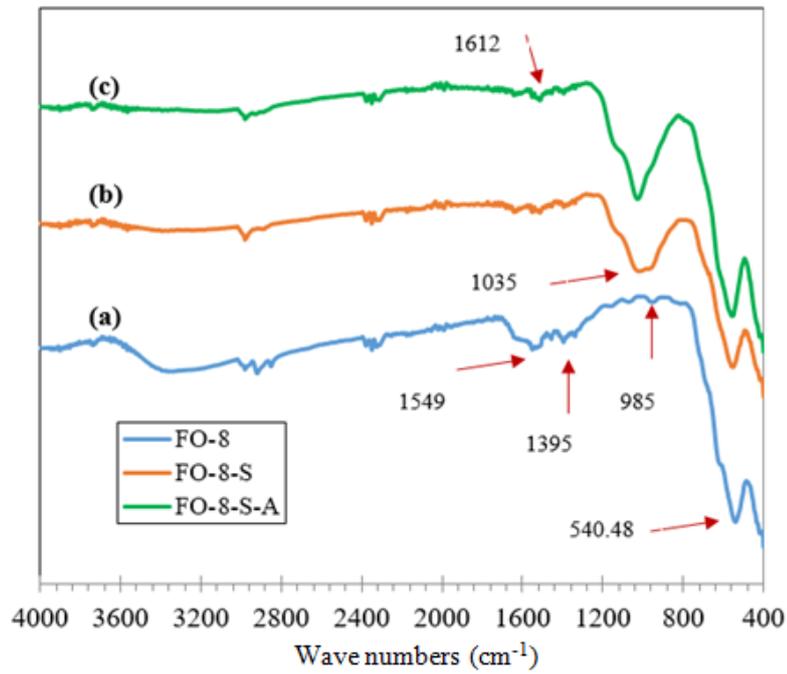

**Figure A.5:** FTIR analysis results of FO-5 samples (a) core, (b) silica coated, (c) aminated.

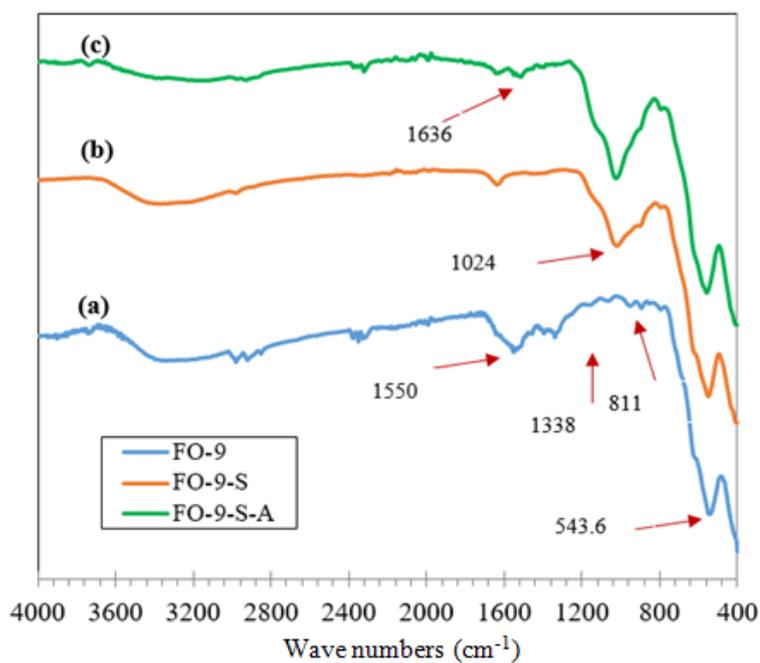

**Figure A.6:** FTIR analysis results of FO-6 samples (a) core, (b) silica coated, (c) aminated.

**Figure A.7:** FTIR analysis results of FO-7 samples (a) core, (b) silica coated, (c) aminated.

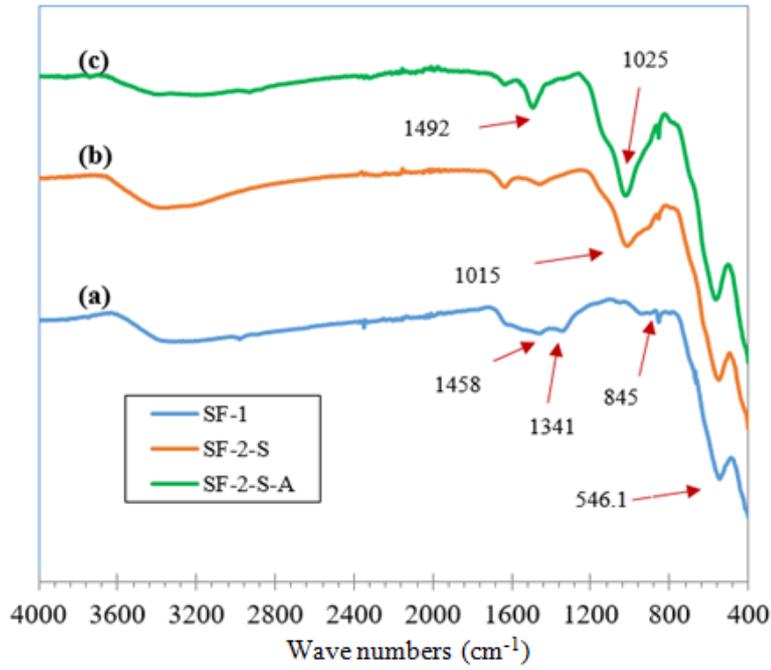

**Figure A.8:** FTIR analysis results of FO-8 samples (a) core, (b) silica coated, (c) aminated.

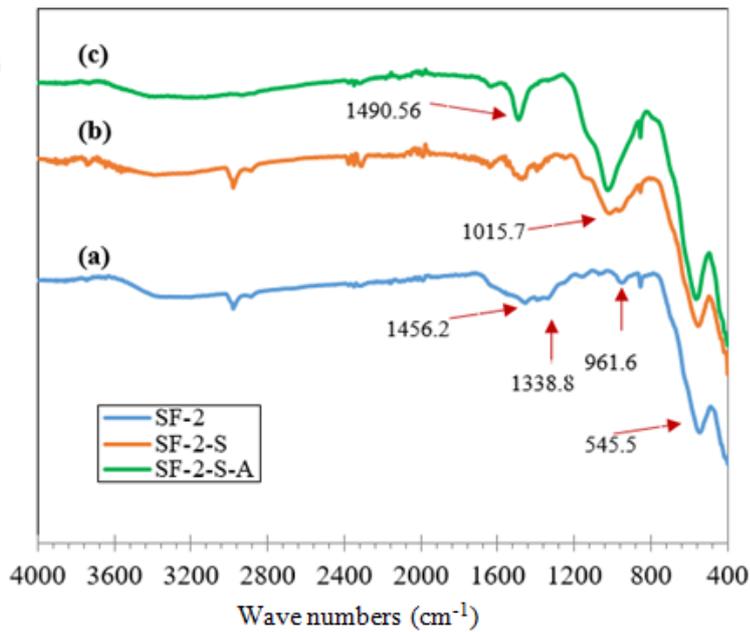

**Figure A.9:** FTIR analysis results of FO-9 samples (a) core, (b) silica coated, (c) aminated.

**Table A.2:** SrFe<sub>12</sub>O<sub>19</sub> magnetic nanoparticles and silica coated and aminated magnetic nanoparticles given codes.

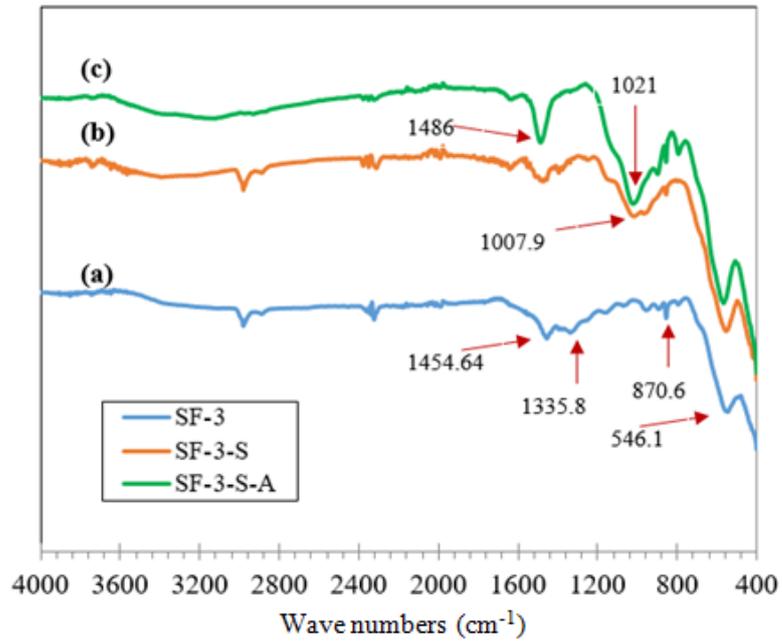

Material	Condition	Code
	Core	SF-1
SrFe <sub>12</sub> O <sub>19</sub>	Silica coated	SF-2-S
	Aminated	SF-2-S-A
SrFe <sub>12</sub> O <sub>20</sub>	Core	SF-2
	Silica coated	SF-2-S
	Aminated	SF-2-S-A
SrFe <sub>12</sub> O <sub>21</sub>	Core	SF-3
	Silica coated	SF-3-S
	Aminated	SF-3-S-A
SrFe <sub>12</sub> O <sub>22</sub>	Core	SF-4
	Silica coated	SF-4-S
	Aminated	SF-4-S-A
SrFe <sub>12</sub> O <sub>23</sub>	Core	SF-5
	Silica coated	SF-5-S
	Aminated	SF-5-S-A
SrFe <sub>12</sub> O <sub>24</sub>	Core	SF-6
	Silica coated	SF-6-S
	Aminated	SF-6-S-A

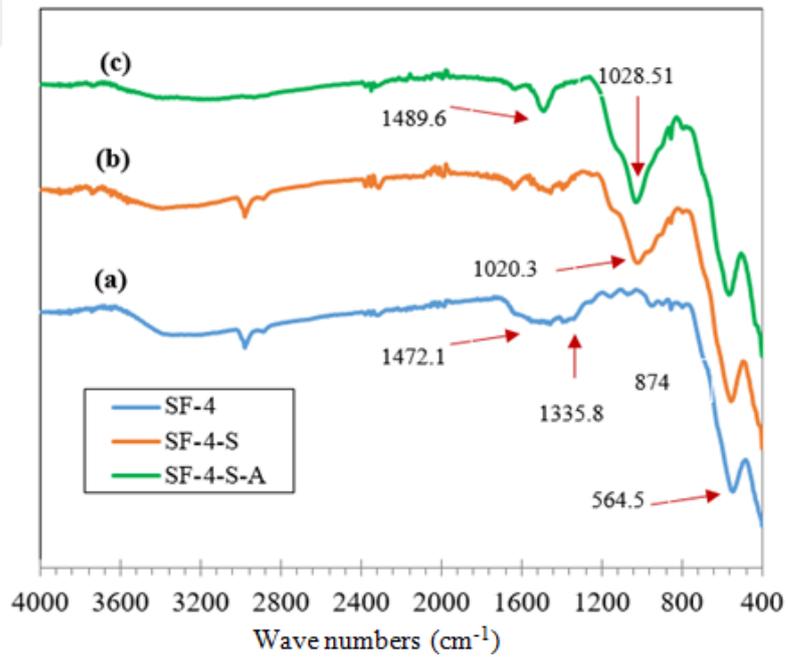

**Figure A.10:** FTIR analysis results of SF-1 samples (a) core, (b) silica coated, (c) aminated.

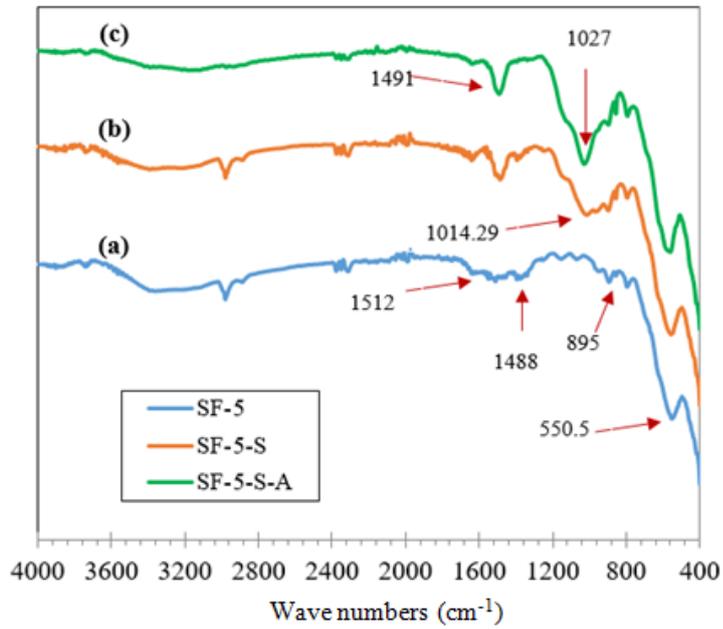

**Figure A.11:** FTIR analysis results of SF-2 samples (a) core, (b) silica coated, (c) aminated.

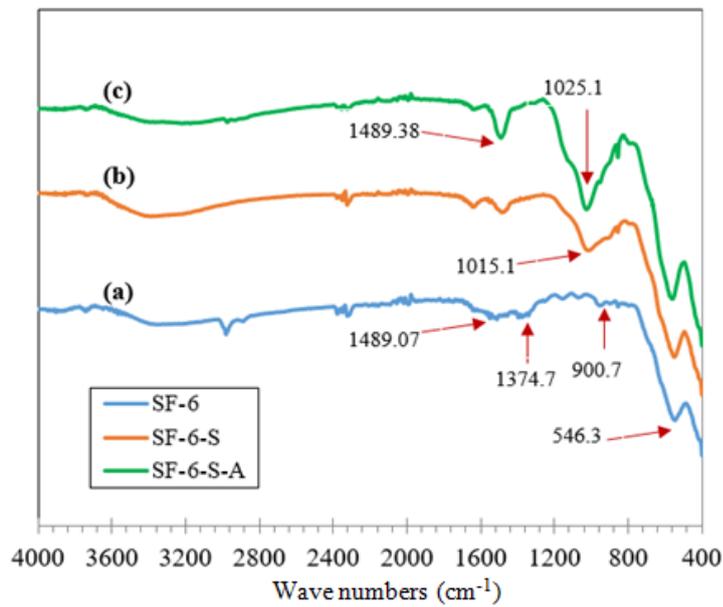

**Figure A.12:** FTIR analysis results of SF-3 samples (a) core, (b) silica coated, (c) aminated.

**Figure A.13:** FTIR analysis results of SF-4 samples (a) core, (b) silica coated, (c) aminated.

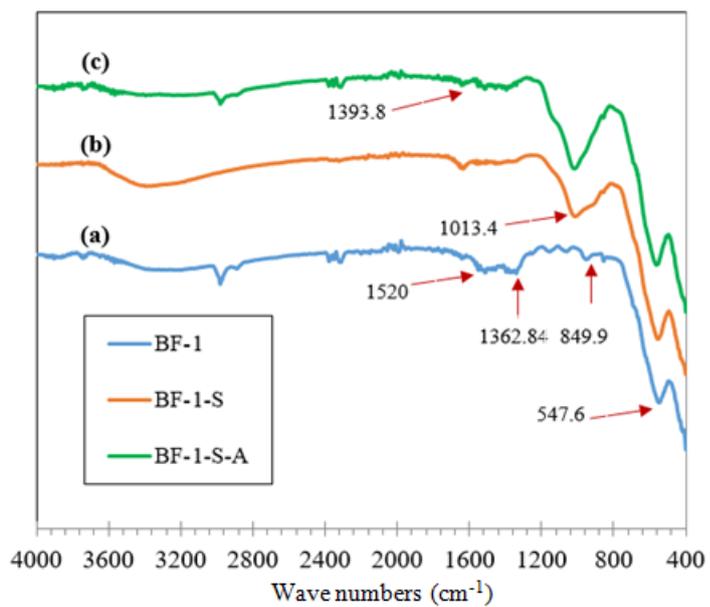

**Figure A.14:** FTIR analysis results of SF-5 samples (a) core, (b) silica coated, (c) aminated.

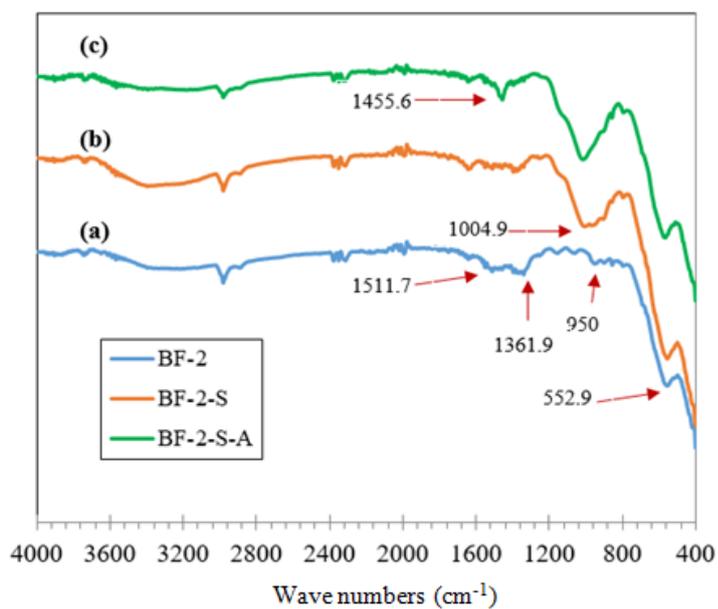

**Figure A. 15:** FTIR analysis results of SF-6 samples (a) core, (b) silica coated, (c) aminated.

**Table A.3:** BaFe<sub>12</sub>O<sub>19</sub> magnetic nanoparticles and silica coated and aminated magnetic nanoparticles given codes.

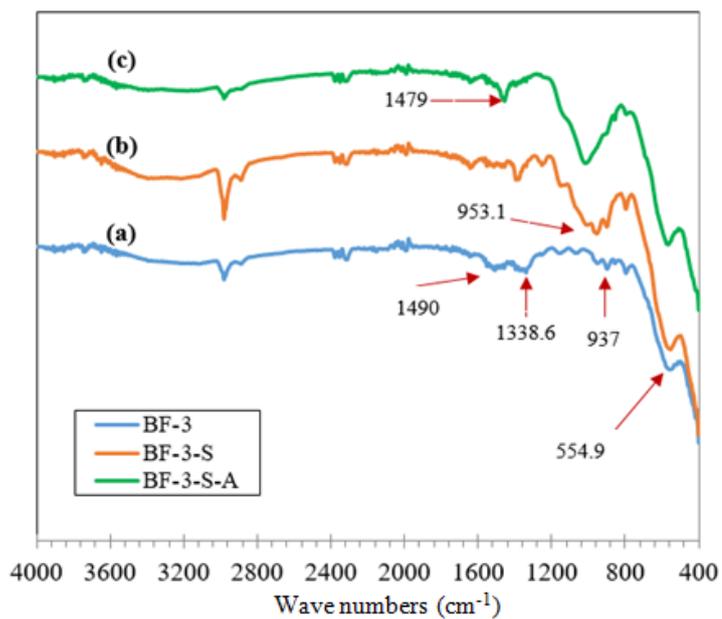

Material	Condition	Code
	Core	BF-1
BaFe <sub>12</sub> O <sub>19</sub>	Silica coated	BF-1-S
	Aminated	BF-1-S-A
	Core	BF-2
BaFe <sub>12</sub> O <sub>19</sub>	Silica coated	BF-2-S
	Aminated	BF-2-S-A
	Core	BF-3
BaFe <sub>12</sub> O <sub>19</sub>	Silica coated	BF-3-S
	Aminated	BF-3-S-A
	Core	BF-4
BaFe <sub>12</sub> O <sub>19</sub>	Silica coated	BF-4-S
	Aminated	BF-4-S-A
	Core	BF-5
BaFe <sub>12</sub> O <sub>19</sub>	Silica coated	BF-5-S
	Aminated	BF-5-S-A
	Core	BF-6
BaFe <sub>12</sub> O <sub>19</sub>	Silica coated	BF-6-S
	Aminated	BF-6-S-A
	Core	BF-7
BaFe <sub>12</sub> O <sub>19</sub>	Silica coated	BF-7-S
	Aminated	BF-7-S-A
	Core	BF-8
BaFe <sub>12</sub> O <sub>19</sub>	Silica coated	BF-8-S
	Aminated	BF-8-S-A
	Core	BF-9
BaFe <sub>12</sub> O <sub>19</sub>	Silica coated	BF-9-S
	Aminated	BF-9-S-A

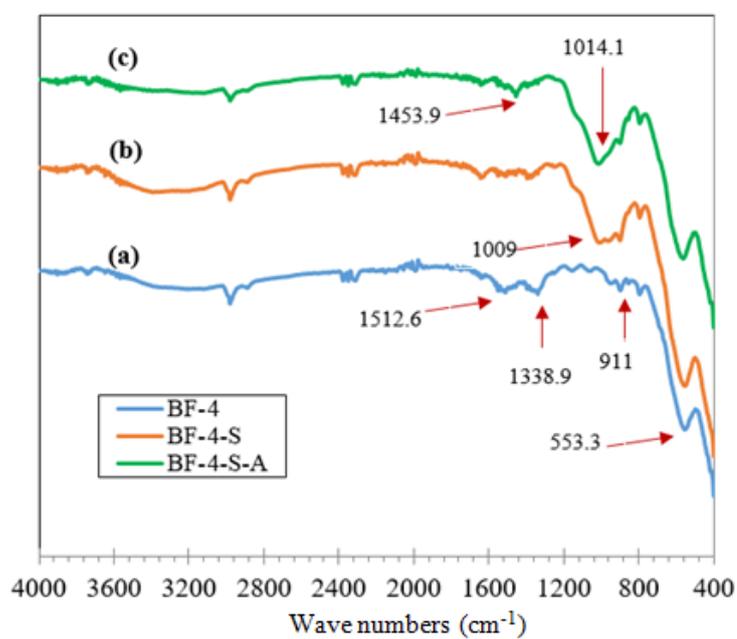

**Figure A.16:** FTIR analysis results of BF-1 samples (a) core, (b) silica coated, (c) aminated.

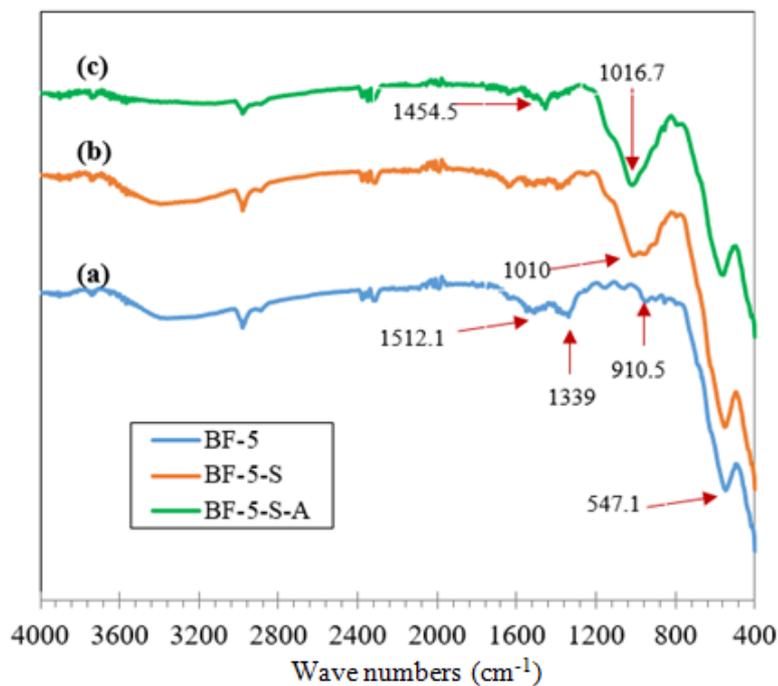

**Figure A.17:** FTIR analysis results of BF-2 samples (a) core, (b) silica coated, (c) aminated.

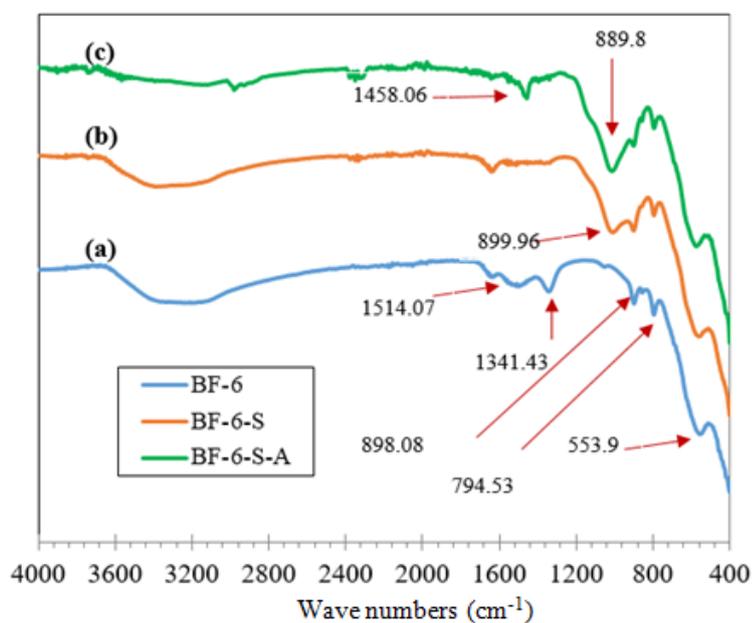

**Figure A.18:** FTIR analysis results of BF-3 samples (a) core, (b) silica coated, (c) aminated.

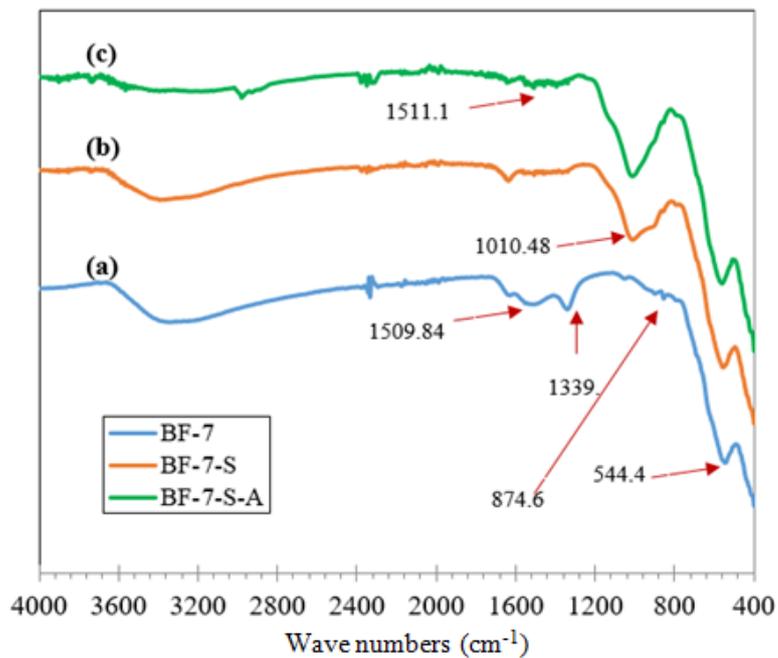

**Figure A.19:** FTIR analysis results of BF-4 samples (a) core, (b) silica coated, (c) aminated.

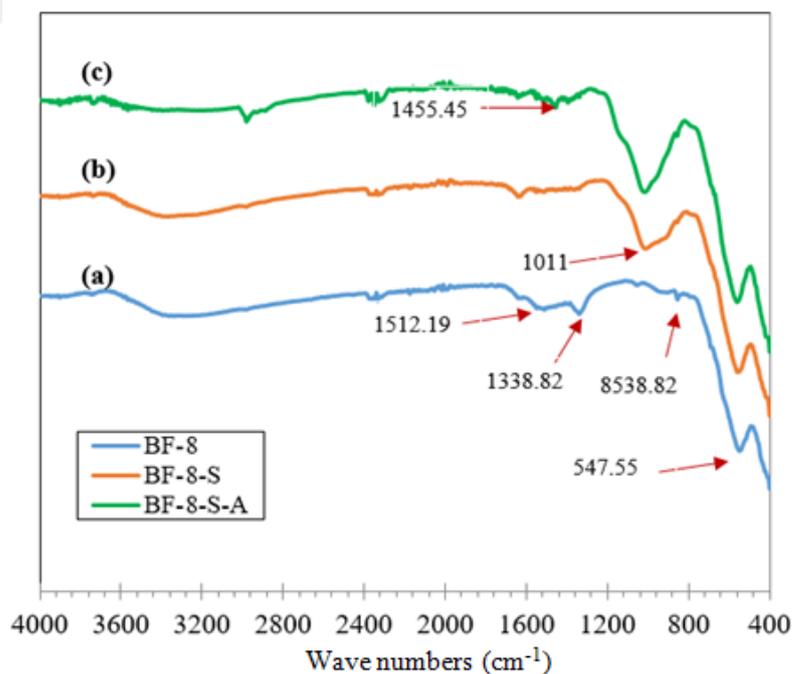

**Figure A.20:** FTIR analysis results of BF-5 samples (a) core, (b) silica coated, (c) aminated.

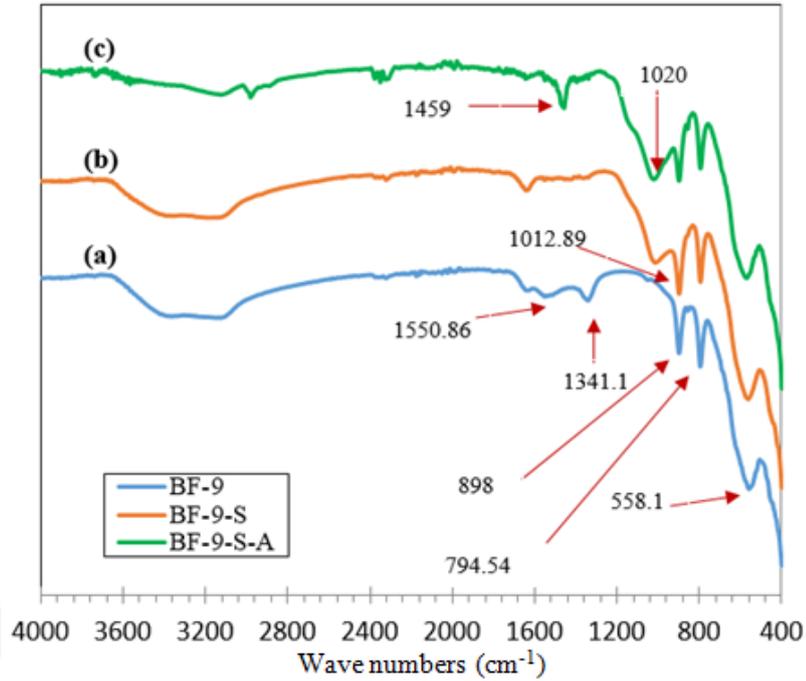

**Figure A.21:** FTIR analysis results of BF-6 samples (a) core, (b) silica coated, (c) aminated.

**Figure A.22:** FTIR analysis results of BF-7 samples (a) core, (b) silica coated, (c) aminated.

**Figure A.23:** FTIR analysis results of BF-8 samples (a) core, (b) silica coated, (c) aminated.

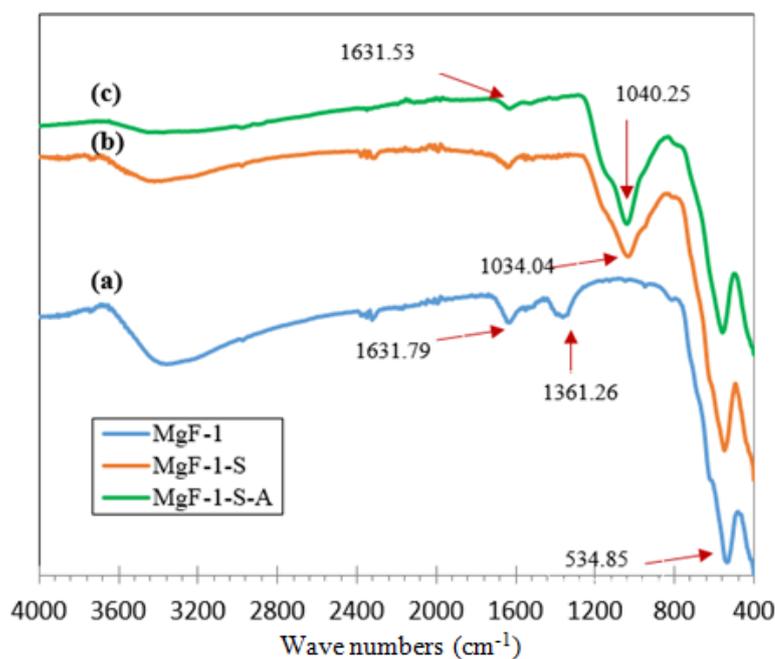

**Figure A.24:** FTIR analysis results of BF-9 samples (a) core, (b) silica coated, (c) aminated.

**Table A.4:**  $\text{MgFe}_2\text{O}_4$  magnetic nanoparticles and silica coated and aminated magnetic nanoparticles given codes.

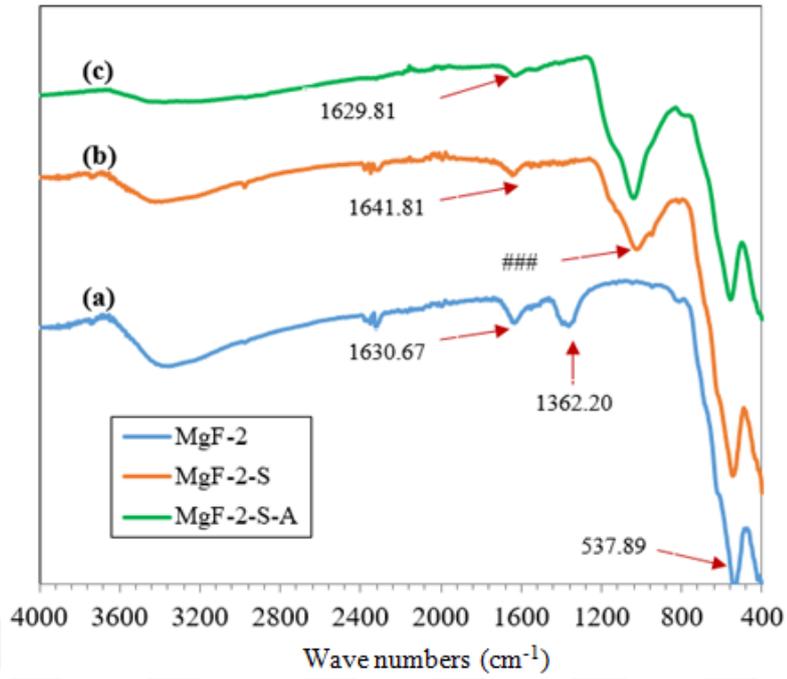

Material	Condition	Code
$\text{MgFe}_2\text{O}_4$	Core	MgF-1
	Silica coated	MgF-1-S
	Aminated	MgF-1-S-A
$\text{MgFe}_2\text{O}_4$	Core	MgF-2
	Silica coated	MgF-2-S
	Aminated	MgF-2-S-A
$\text{MgFe}_2\text{O}_4$	Core	MgF-3
	Silica coated	MgF-3-S
	Aminated	MgF-3-S-A
$\text{MgFe}_2\text{O}_4$	Core	MgF-4
	Silica coated	MgF-4-S
	Aminated	MgF-4-S-A
$\text{MgFe}_2\text{O}_4$	Core	MgF-5
	Silica coated	MgF-5-S
	Aminated	MgF-5-S-A
$\text{MgFe}_2\text{O}_4$	Core	MgF-6
	Silica coated	MgF-6-S
	Aminated	MgF-6-S-A

**Table A.4 (continued):** MgFe<sub>2</sub>O<sub>4</sub> magnetic nanoparticles and silica coated and aminated magnetic nanoparticles given codes.

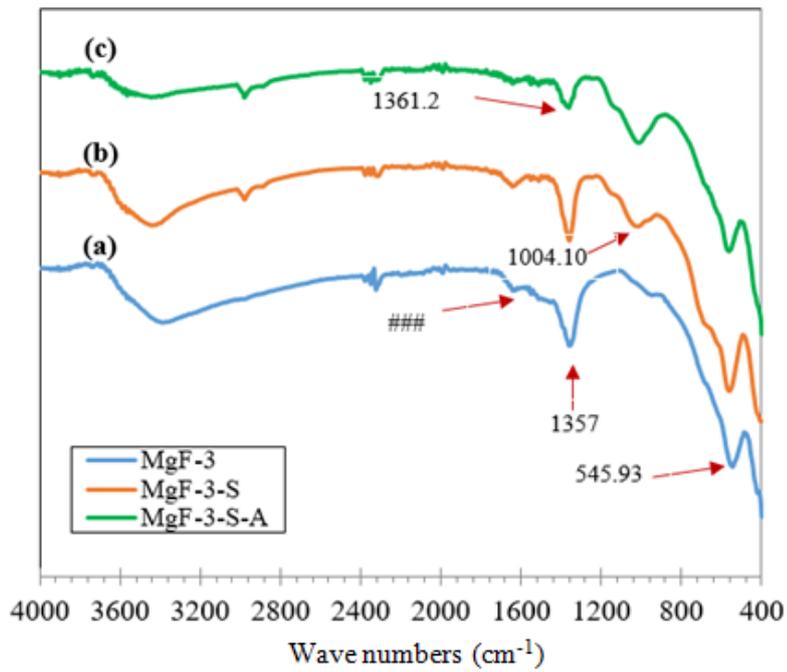

Material	Condition	Code
	Core	MgF-7
MgFe <sub>2</sub> O <sub>4</sub>	Silica coated	MgF-7-S
	Aminated	MgF-7-S-A
	Core	MgF-8
MgFe <sub>2</sub> O <sub>4</sub>	Silica coated	MgF-8-S
	Aminated	MgF-8-S-A
	Core	MgF-9
MgFe <sub>2</sub> O <sub>4</sub>	Silica coated	MgF-9-S
	Aminated	MgF-9-S-A
	Core	MgF-10
MgFe <sub>2</sub> O <sub>4</sub>	Silica coated	MgF-10-S
	Aminated	MgF-10-S-A
	Core	MgF-11
MgFe <sub>2</sub> O <sub>4</sub>	Silica coated	MgF-11-S
	Aminated	MgF-11-S-A
	Core	MgF-12
MgFe <sub>2</sub> O <sub>4</sub>	Silica coated	MgF-12-S
	Aminated	MgF-12-S-A

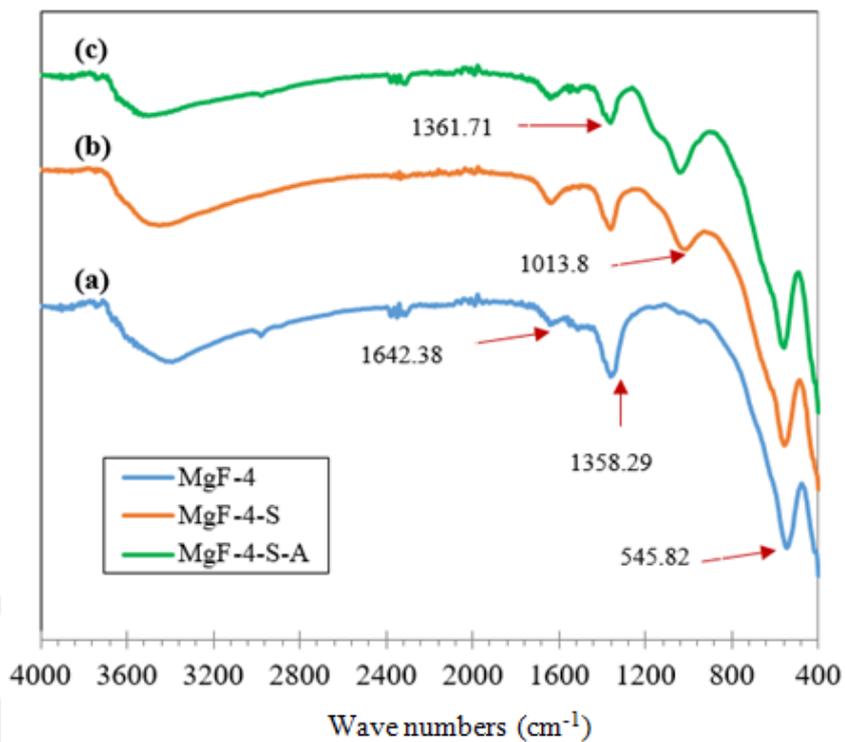

**Figure A.25:** FTIR analysis results of MgF-1 samples (a) core, (b) silica coated, (c) aminated.

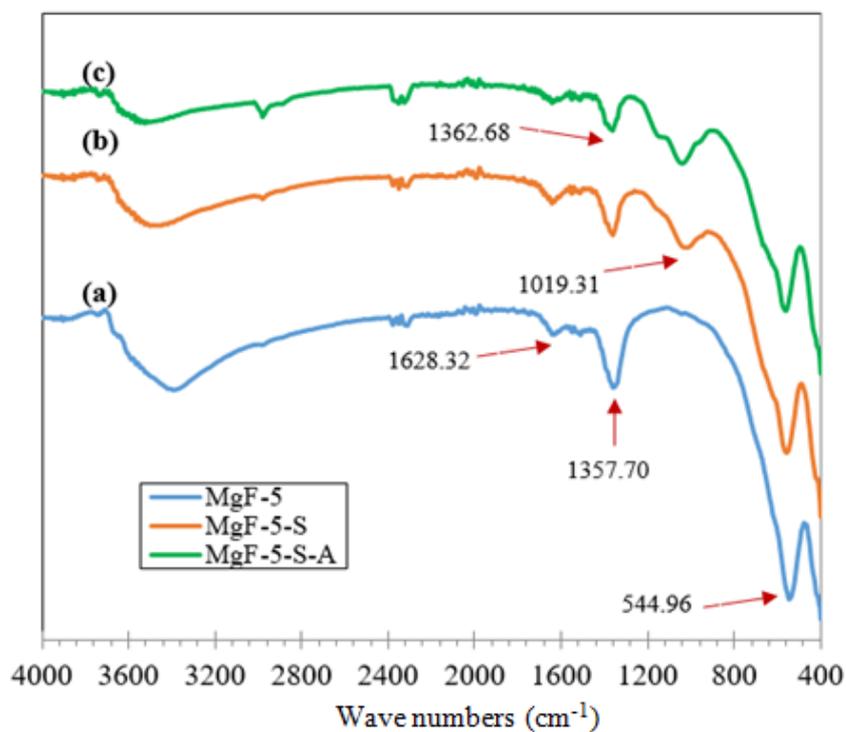

**Figure A.26:** FTIR analysis results of MgF-2 samples (a) core, (b) silica coated, (c) aminated.

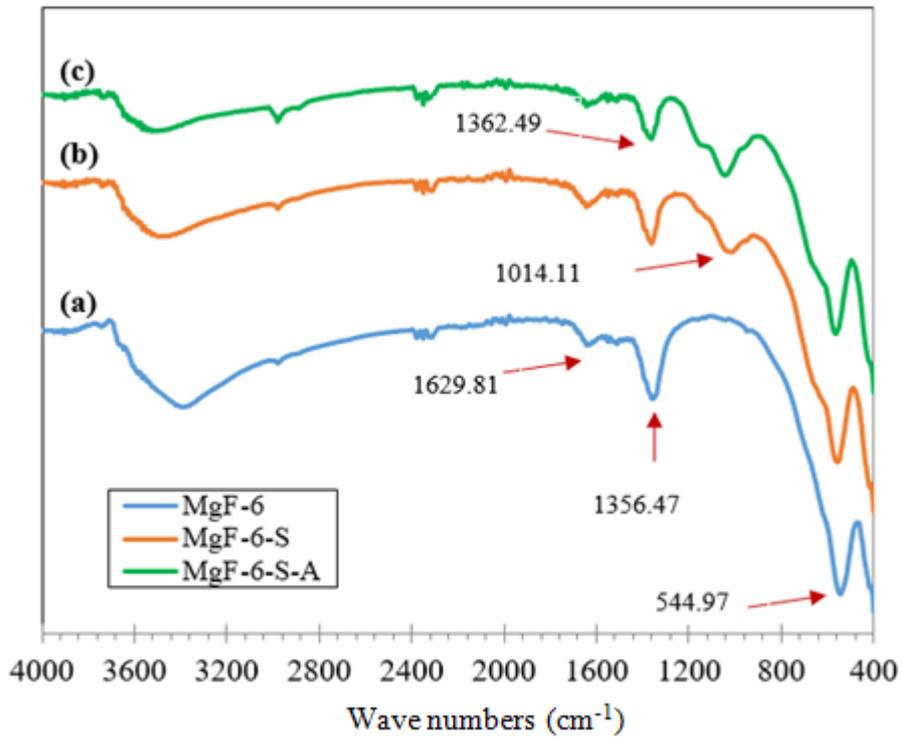

**Figure A.27:** FTIR analysis results of MgF-3 samples (a) core, (b) silica coated, (c) aminated.

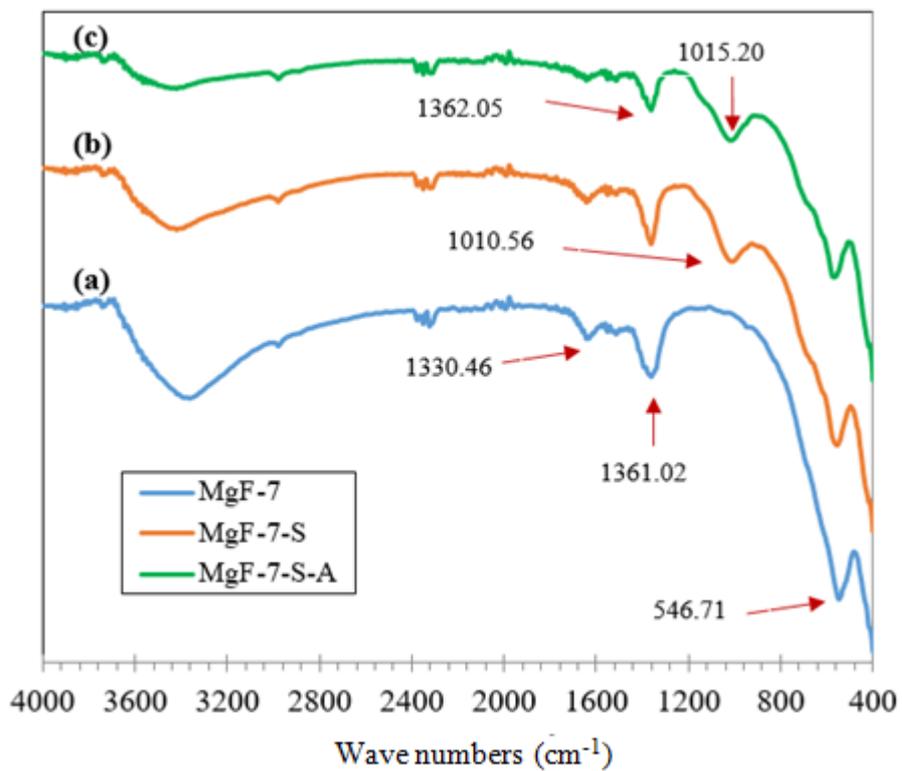

**Figure A.28:** FTIR analysis results of MgF-4 samples (a) core, (b) silica coated, (c) aminated.

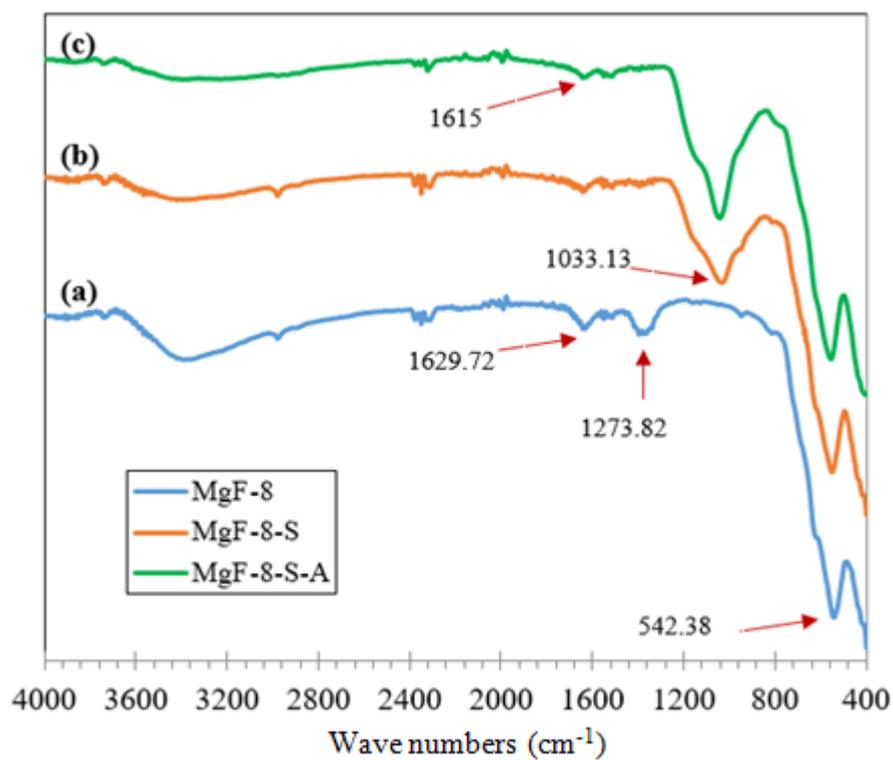

**Figure A.29:** FTIR analysis results of MgF-5 samples (a) core, (b) silica coated, (c) aminated.

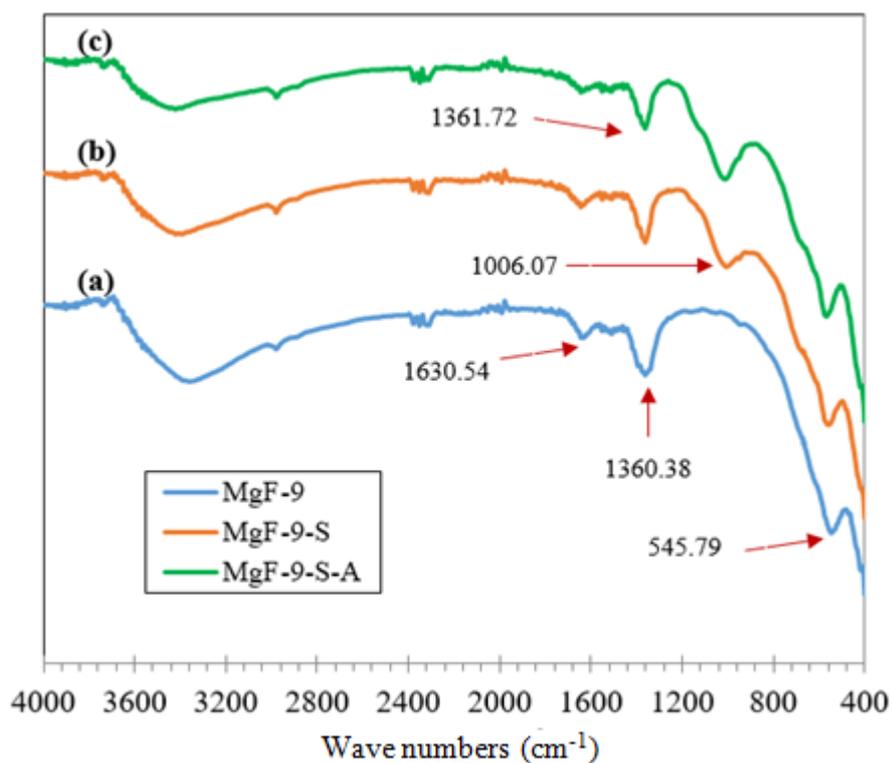

**Figure A.30:** FTIR analysis results of MgF-6 samples (a) core, (b) silica coated, (c) aminated.

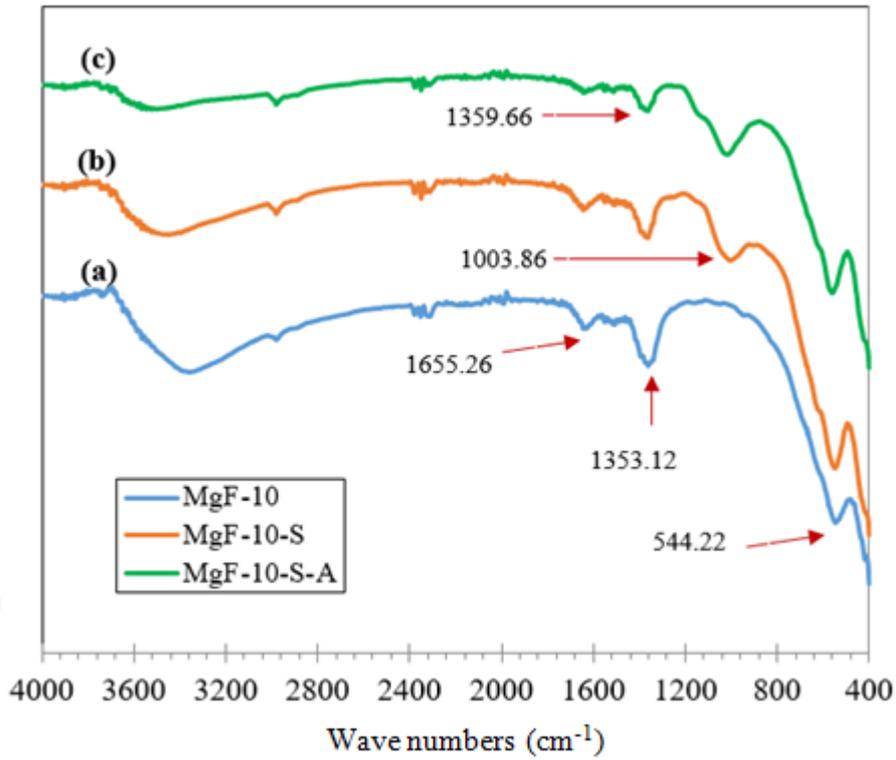

**Figure A.31:** FTIR analysis results of MgF-7 samples (a) core, (b) silica coated, (c) aminated.

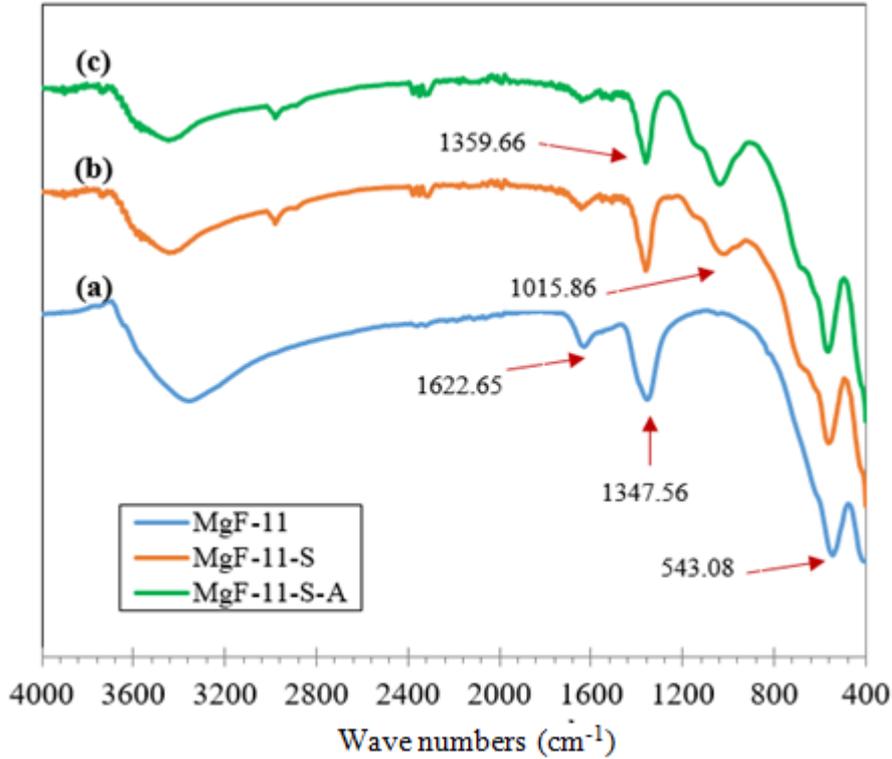

**Figure A.32:** FTIR analysis results of MgF-8 samples (a) core, (b) silica coated, (c) aminated.

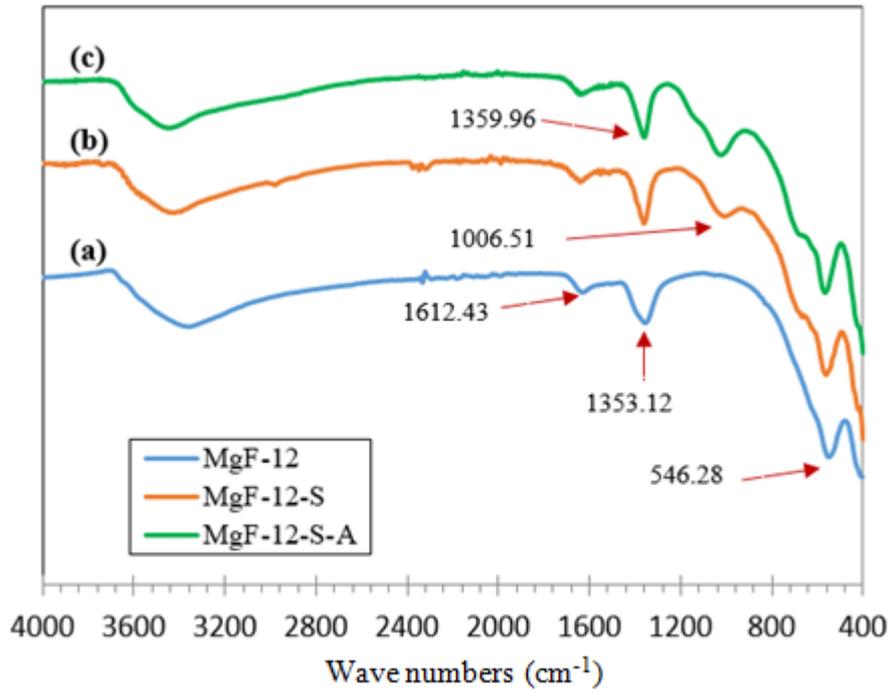

**Figure A.33:** FTIR analysis results of MgF-9 samples (a) core, (b) silica coated, (c) aminated.

**Figure A.34:** FTIR analysis results of MgF-10 samples (a) core, (b) silica coated, (c) aminated.

**Figure A.35:** FTIR analysis results of MgF-11 samples (a) core, (b) silica coated, (c) aminated.

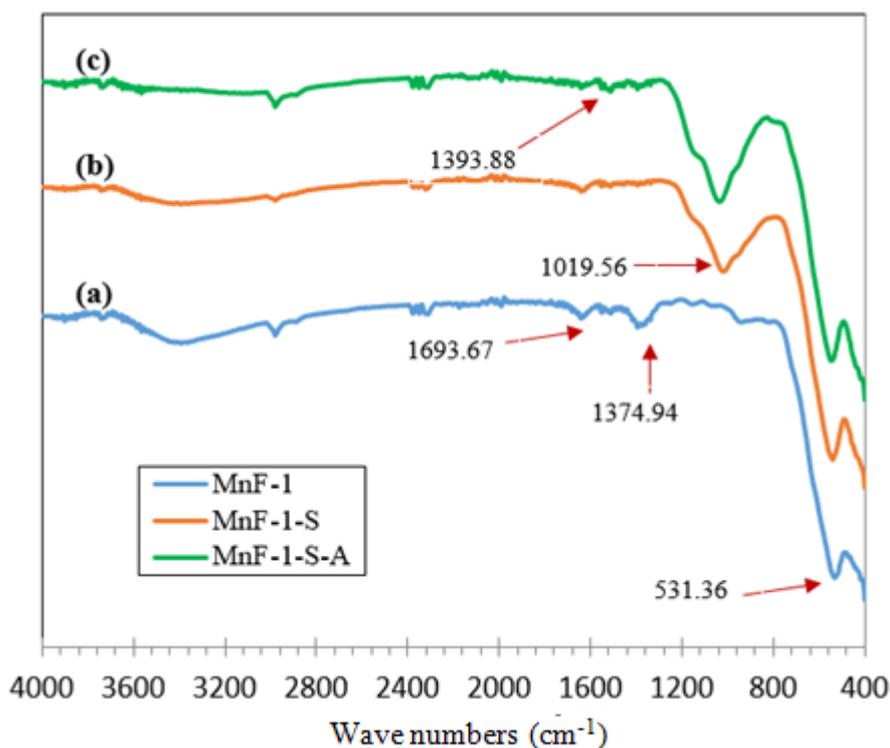

**Figure A.36:** FTIR analysis results of MgF-12 samples (a) core, (b) silica coated, (c) aminated.

**Table A.5:** MnFe<sub>2</sub>O<sub>4</sub> magnetic nanoparticles and silica coated and aminated magnetic nanoparticles given codes.

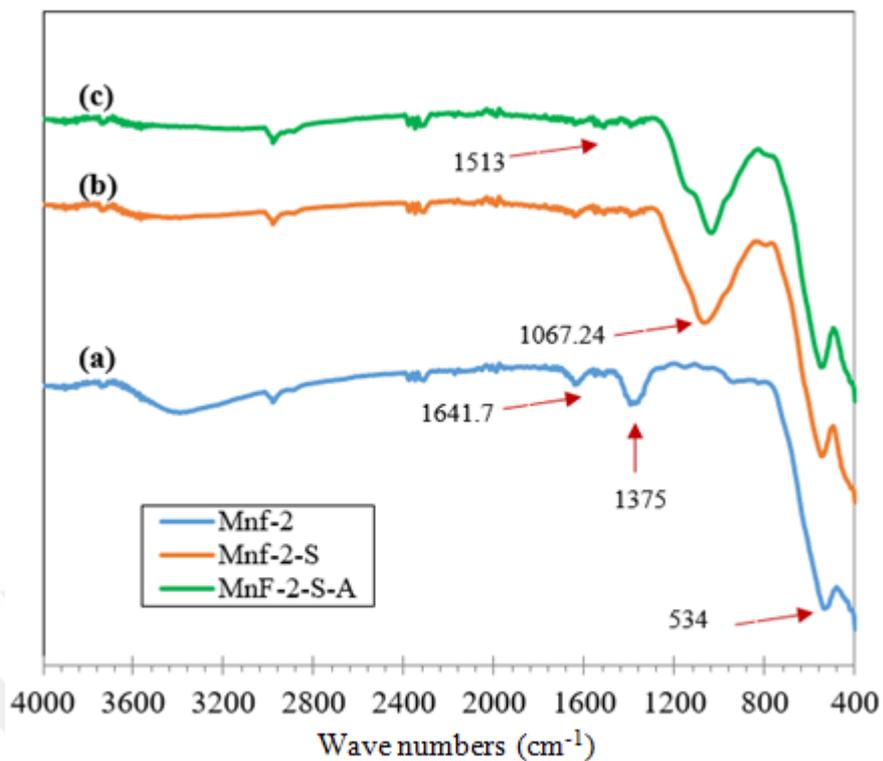

Material	Condition	Code
MnFe <sub>2</sub> O <sub>4</sub>	Core	MnF-1
	Silica coated	MnF-1-S
	Aminated	MnF-1-S-A
MnFe <sub>2</sub> O <sub>4</sub>	Core	MnF-2
	Silica coated	MnF-2-S
	Aminated	MnF-2-S-A
MnFe <sub>2</sub> O <sub>4</sub>	Core	MnF-3
	Silica coated	MnF-3-S
	Aminated	MnF-3-S-A
MnFe <sub>2</sub> O <sub>4</sub>	Core	MnF-4
	Silica coated	MnF-4-S
	Aminated	MnF-4-S-A

**Table A.5 (continued):** MnFe<sub>2</sub>O<sub>4</sub> magnetic nanoparticles and silica coated and aminated magnetic nanoparticles given codes.

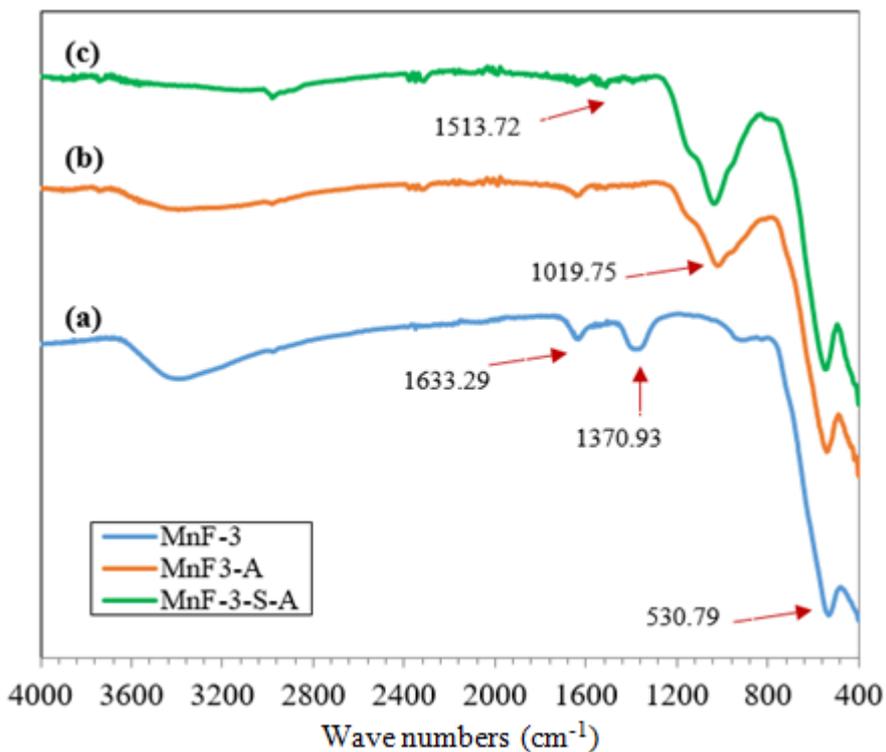

Material	Condition	Code
MnFe <sub>2</sub> O <sub>4</sub>	Core	MnF-5
	Silica coated	MnF-5-S
	Aminated	MnF-5-S-A
MnFe <sub>2</sub> O <sub>4</sub>	Core	MnF-6
	Silica coated	MnF-6-S
	Aminated	MnF-6-S-A
MnFe <sub>2</sub> O <sub>4</sub>	Core	MnF-7
	Silica coated	MnF-7-S
	Aminated	MnF-7-S-A
MnFe <sub>2</sub> O <sub>4</sub>	Core	MnF-8
	Silica coated	MnF-8-S
	Aminated	MnF-8-S-A

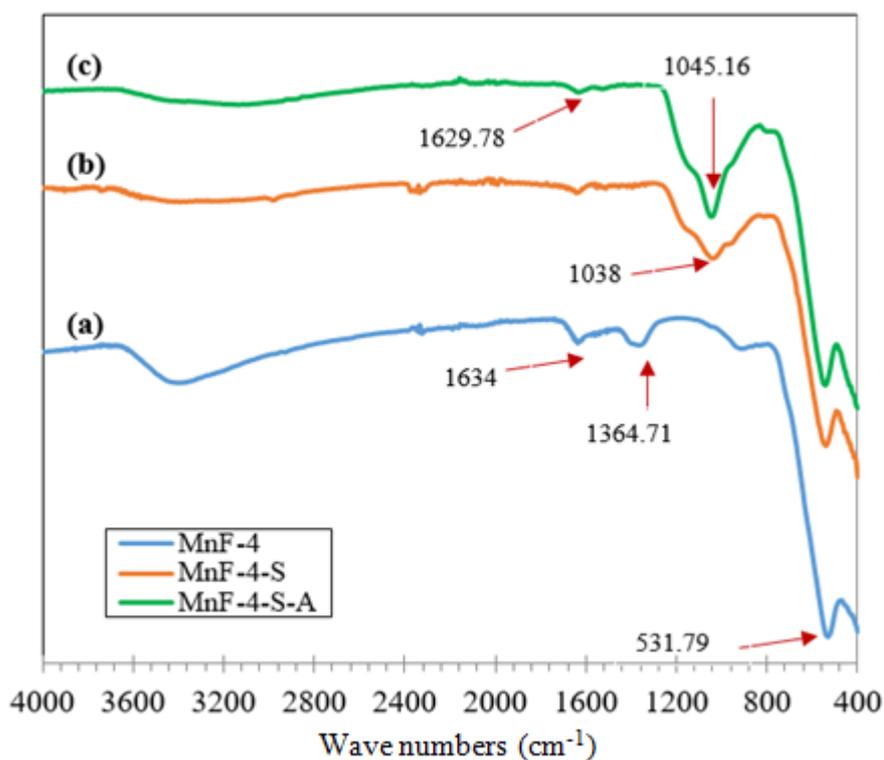

**Figure A.37:** FTIR analysis results of MnF-1 samples (a) core, (b) silica coated, (c) aminated.

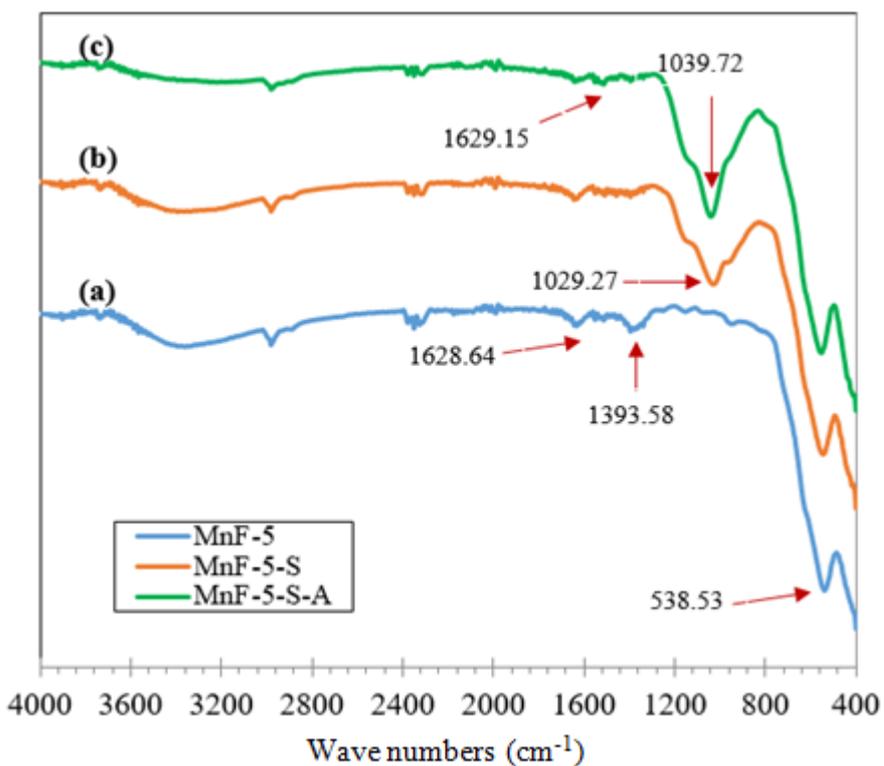

**Figure A.38:** FTIR analysis results of MnF-2 samples (a) core, (b) silica coated, (c) aminated.
